PUBLIC LIBRARY 1850

INDEX OF CONTENTS

TO THE

GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE,

For 1844.

A

Anise religiosa, hardiness of, 335; — Douglasii at Monark, death of, 573
Abutilon striatum, 104; vitifolium, 799
Acarus hortensis, 316
Achimenes pedunculata, 7; grandiflora, 8
Acer rubrum, 276
Acorns as food for pigs, 699, 772; their use, 830
Acorus Calamus, 796
Adelaide, Table of the Weather at, for 1842, 319
Adulteration of Wheat flour, 386; of manures, 222, 259, 301, 377, 393, 416, 453; of guano, 485, 774.
Aerides virens, 574
Alluvial inclosures, 14
Agriculture, its practice with profit, by H. Newnham, rev., 661; in New South Wales, by J. Atkinson, rev., 237; in France, 142; application of science to, 610; mechanics applied to, 219; anomalies of, 690, 705, 769, 737; lectures on, by A. Petzholdt, rev., 719; by G. Cox, rev., 767; Davy's, by J. Shier, rev., 734; relative position of, 786; of Norfolk, by R. N. Bacon, rev., 789; Application of Geology to, by N. Whitley, rev., 141; Scotch, 170; Manx, 53, 122, 130; and geology, 234, 249, 266; in China, 220
Agricultural colleges, 14; education, 27, 30, 49, 301, 341; value of land, 57, 73, 89; improvements, 155, 221, 281, 413, 434, 487; ditto in modern husbandry, 109; experiments, 305, 857; leases, 341; implements, 449, 466, 641; ditto, to preserve, 723; implement clubs, 709; implements, adv., Wedlake, 175; chemistry association, 469, 480, 724; plants, composition of, 349; mechanics, 609; remarks on, 577, 689; societies, advantages of, 625, 747; weeds, 302; chemistry, by J. F. W. Johnson, rev., 470; Grasses of Ireland, by D. Moor, rev., 193; college at Cirencester, 308, 460; improvement, capabilities of, in Hampshire, 598; chemistry, remarks on, 804; co-operation, 9, 77; character of coal, 691; of fullers' earth, 577; of limestone, 722; of masistone, 593; of millstone grit, 691; of red sandstone, 644, 754
Agricultural Gazette, prospectus of, 9; 1st vol. of, 873
Agrimony, remarks on, 412
Agromyza viola, 244
Air necessary for roots of plants, 30
Alexandra imperatricis, 718
Alkalies a manure, by H. Waterton, rev., 157
Allotment system, 203, 469, 562, 613, 628, 642, 675; beneficial effects of, 677; remarks on, 645, 673, 690, 705, 707, 746, 756, 771; in Ireland, 755; cottage, 593; tendencies of, 377; effect of, 836; objections to, 839
Almond a fruit for the dessert, 765
Alnus cuspidata, 622
Alpaca of Peru, 439; to naturalise, 580; Walton on its naturalisation, rev., 613
Alum, its manufacture, 598; as manure, 724
Amaryllis Maloney, 295, 357; forcing pit, 732
America, Central, some of the productions of, 871
American plants, 276; tree and shrub seeds, adv., Charlwood, 176; Phillips, 193; notes on, 501, 691, 804
Anchusia undulata, 21
Ammonia, to fix, 46, 76, 253, 461, 469, 505; in liquid manure, 438; by gypsum, 467, 722, 742, 773, 850; by soil, 437; by salph. acid, 467; losses of, 571; as manure, 598, 869
Ammoniacal liquor as manure, 870
Ammonite Bucklandiana, 736
Anchovies, of pure nature, 736; of Dutch ditto, 736; of South ditto, 736; of Spanish ditto, 736; of extract of anchovies, 736; of [illegible], 736; of [illegible], 736; [illegible], 736
[illegible], 736
[illegible], 736
[

INDEX.

[redacted] of, 451; ranking of, [redacted] more for [redacted], 760; more for [redacted] to stone, 178; [redacted], best sorting [redacted], Fitz-roya as, [redacted] ditto, Tortilis [redacted] [redacted] to kill, law concerning, [redacted] for straw, [illegible] 797
[redacted] of, 405; influence of Vi[redacted] to kill, law concerning,
Cambridge, Walcherton, adv., Merrick and Manley, 1
Carbate, to improve, 182; to prune, 764; of Lemons, seeds of, to make germinate, 643
Celeriac, treatment of, 136; remarks on, 184
Celery, treatment of, 72, 219; to earth up, 640
Cement, 197; marble, Roy, Keques's, 159
Cerastium, monstrosity of, 557
Cercis canadensis, 276
Cereus seedling, noticed, 783
Chalk, to apply to land, 98; its use in improving clay soils, 737, 753, birth, 156
Chalking land, remarks on, 753, 803
Chandler's nursery, noticed, 231, 763
Channel islands, 529
Charcoal for plants, 8; experiments with, 310; effects of on plants, 69; to make, 184, 730, carbonic acid condensed by, 71; remarks on, 295; ancient, remarks on, 505, and salt, their effect on Turnips, 499, past, to manufacture, 369, ditto as a top-dressing for land 467
Chatsworth, gardens at, noticed, 734
Cheese, importations of, 676, Dutch, flavour of, 724
Chelmsford wool fair, 492
Chemistry Association, 207, 479, 489, 724
Chemistry, to apply to agri, 27, 43, 59 75, 91, 106, 122, 139, 154 170, 186, 203 235, 267, 283, 303, 344; of cultivation, 247, 298, and agri, 309, remarks on 404; agricultural, by J F. W Johnson, rev., 170; by G Cox, rev, 767; by Prof. Low, rev., 103; practical organic, Picker ing, rev., 55
Chepstow Farmers' Club, report of, rev., 51
Cherries, kinds for an orchard, 344
Chesnut, fruited, Oak gall fly, 212
Chicory, culture of 203, 294, 317, remarks on, 324, 358; to prepare 360
Chickweed, to destroy, 46
China, news from, 103, Canton, celebration of [redacted] year at, 505; Fatee gardens near Canton, 590, Textile plant from, 151
Chinese agri, 220, seeds, remarks on, 405
Chocolate, 7
Chocolate tree and its uses 835
Chrysanthemums, kinds to save seed from, 24, select, 72, guano for, 575, effect of liquid guano on 765; treatment of, 814
Churn, Sussex, adv., Barnes & Co, 159
Cider, antiquity of in Normandy, 843
Cinerarias, adv, Brewer, 1; culture of, 527; select, 624
Cirencester agri college, 308, 469
Citron a remedy for poison, 97
Citrus tribe, culture of, 244
Clay land, to crop 26; burning of 549, to prepare for Turnips, 77; to drain, 707, management of, 878
Clematis montana, 7
Clianthus puniceus, 638
Climbers, greenhouse 72, 300; hardy, 120, select, 152, list of, 392, 412
Clitoria fulgens, 405
Clover dodder, 29, 629, 820 remarks on, 625
Clover, Dutch, 70; red, failure of, 529, seeds, to sow, 454
Clubbing in Cabbages, to prevent 640
Coal, burning of, 51, 99, agri character of, 691; trade, 153
Coccinella septem punctata, 588
Cocous Viris, to kill 24
Coffee improved by carbonate of soda, 559, 835
Colleges, agricultural, 14, at Cirencester, 308, 469
Collier's Wood, Tooting gardens at, noticed, 247
Colours by candlelight, 524
Commelina celestis 56
Compost heaps, to form, 512
Coniferæ remarks on, 218 300 557, 606; to graft 339; Highland Pine, adv, Grigor 161 azotised matter injurious to 484, of Japan 725, 5 5 Mexican, 240, hardiness of, 315, 372, 390 growth of, in Morayshire, 663
Concrete tiles, 13
Conservatories, plants for 940 with fixed roofs, 504, subjects fit for culture in 859
Co-operation experimental, 9; between farmers and chemists 77
Convallaria racemosa, 632
Coppices, to plant 72, Birch, 819, ditto, to manage, 860, hints on renovating, 811; management of, 813
Coprolites, 10; to apply as a manure, 43, 91
Corethrosyrilis bracteata, 607
Corn, Indian, 365; to save, in damp weather, 549, steep for, 582; transmutation of, 555 573 621, 629, 692 779, to sow, 595 waste of, in thick sowing, 669, mode of harvesting, in East Lothian, 611; Davies, on the waste of, rev, 669, experiments with, 26
Corn weevil 13
Cornus florida 276
Cotswolds farming on, 736
Coughs, Bitchound, a remedy for, 375
Country Shows 219 315; remarks on, 103
Couve tronchou a 120
Covering for greenhouses, 214; for flower beds, 248, for fruit trees, 98, for frames, 302, 704 707, 708
Cow-houses, ventilation of 130
Cow [redacted]pat, 171
Cow [redacted]ouage, 237
Cows, fattening properties of [redacted] to stall-feed, 304, 306; Swedish by Turnips 91, dairy, winter food for, 316, 579; oil cake as food for, 712; to feed, 675
Cowslips, remarks on, 373
Cox on Agricultural Chemistry, rev, 767
Cream, bitter flavour of, 708
Crocuses, 216
Cropping, course of, 142; old system of, 420
Crops, best sorts of, for spring food, 642, 657 two, per annum, 797, 756, on the same land in successive years, 723; rotation of, 190, 486, 660 value of, 156, 285, state of, 465; appearance of, 545; failure of 613; in East Lothian, 674; Barley, to secure, 721; galvanism, to apply to, 598.
potatoe of, in East Lothian, 699; to prevent from hazel and rabbits, 600
Cruciferæ, British, by T. Bell, rev., 616
Cryptogamia, plants of Dr. Klotzsch, forming part of the "Flora Indica," by W. Griffith, rev., 218
Cuckoo, remarks on, 250
Cucumbers, to grow, 3, 22, [illegible] of, 73; remarks on, 148, soil for, 726; winter culture of, by J. Moor, rev., 1[illegible] mode of [illegible] from 446, rules for, 1[illegible] 565
Cucumber frames, steam to, 85; flannel, bulk water, superiority of, 599
Cucullo linearis 389
Currant, sporting of, 67
Currant trees as standards 6, 21; to graft, 300, Cuttings to handle in India, 197, to strike, 392, 699, action of light and moisture on, 715, in charcoal, 410; to prepare, 440; to keep a moist atmosphere for, 590
Cymbalium pendulum, var brevifabre, 318
Cynips Quercus castanea, 212, Quercus pedunculi, 499
Cypripedium, hardy, 280

D

Dahlias, select, 340, adv, Harrison, 17, Drummond, 17, Keynes, 17, Bushell, 17, Ansell, 21; Spary, 83, Whales, 53, Girling, 68, Oliver 68, Syred, 81, Daniel, 139; Brown, 139, Jones, 151, Smith, 177, to render hardy, 236
Dairy, management of 170
Dalvey Gardens, near Forres, noticed, 639
Daniel's manure, 451
Darnel poisonous, 279
Dart moths, remarks on, 619
Datura arborea, 136
Davies on the waste of Corn, rev, 669
Davis's system of farming, 804
Davy's Agri Chemistry, by J Shier, rev 734
Deadly Nightshade, poisonous effects of, 654
De Candolle's Prodromus, 318
Denton's Alevel, 754
Deodar, to graft, 40, to strike, 104; large plantation of, 318
Derby Arboretum, noticed, 318
Dialogue on Instinct, by Brougham, rev, 782
Dickson, Mr, his Tulips noticed, 298
Dictionary of the Farm, rev., 457
Dilophus febrilis, 668
Disease, functional, 180, 214
Diseases of plants, 93, 99, 131, 148, 227, 587, 636 643, 715, 764 796, 851, of Potatoes, 163, of sheep, by W C Spooner, rev., 469
Distemper in cattle, cure for, 693
Dogs, distemper in, 318; scent of, for game, 766
Dog rose, remarks on, 637, fruit of, 669
Doryanthes excelsa 152
Double white Hepatica, 217
Draat's Meteorological Ephemeris rev, 622
Drains, remarks on, 19, depth of, 772; made of peat, 904
Drain pipes socket, 788
Drain tiles, cost of, 27, remarks on, 331
Draining, thorough, 45, 517; report on, 710, theoretical views on 520, 657; effects of, 91, on heavy land, 562, 707, materials for, 108, 171, Deanston system of, 725, tile, remarks on, 724; furrow, 125, application of geology to, 397, at Castle Shane, Monaghan, 693, 745, advantages of, 449, remarks, 612, 644, 675, deep, advantages of, 13
Drainage, 468 529; material for, 562, for garden pots, 575
Drainage and irrigation, 840
Draught, remarks on, 186, 609, 638
Drilling wide, 152, 628, thin, 862
Drummond's Museum, 466
Dry rot in timber, 200, 794, 870
Dublin Botanic Garden, noticed, 799
Duke of Cleveland on leases, 19
Dye, new Indian black, 119, new English, 463, vegetable, [redacted]5
Dynamometers remarks on, 880, Cottam's, 593, Clyburn's, 593

E

Earth, instance of its being eaten by a cow, 284
Earth-worm fly, 275
Earthenware pipes, to joint, 797
Earwigs, to trap, 432, 560
East Lothian Husbandry, 302, 323, 343, 362, 378, 394, 414, 435, 449, 466, 487, 511, 531, 611, 626, 643, 674, 706, 722, 739, 771, 787, 802, 839, 858, 874
Echites grassinoda, 687
Economical Polish beverage, 167
Edgings, Heath for, 102, 173, 166
Edinburgh Botanic Garden, noticed, 871
Education, scientific, 466, agricultural, 27, 30, 49, 201, 341
Elæagnus reflexa, 23, parvifolia, fruit of, 571
Electricity, influence of, on the growth of plants, 741
Elm, deformity in, 277
Elm roots, effects of frost on, 87
Elm-gall aphis 47
Emigration, 104
Engine houses for plants, 101; plants for, 184
England southern and western, journey through 596
English Larch and Scotch Pine, 61
Entomology—*See* Insects
Entry, valuations on, 265
Epacris autumnalis, 703
Epidendrum radiatum, 667
Eranthemum pulchellum, 247
Erica Bowbandæ, 298
Erica Murrayana, 318
Eriocoma bursaria, 164
Essay on Flax, by J Sproule, rev, 228
Eucalypti, at Northwood Park 199
Eucharidium grandiflorum, adv., May, 129
Euonymus japonicus, 66
Euphorbia Jacquiniflora, 495
Evergreens, 6
Ewes and lambs, 77
Excrescences on timber, 32

[illegible] with peas, 25, with Potatoes, [illegible] with rape, 144, 162, 183, 847; in Essex, by J Parkes, 227, 240
[illegible] 1[illegible]
[illegible] 1[illegible]
[illegible] 1[illegible]
[illegible] 1[illegible]
Fences, superintendence of, 869
Fencing, Bergerac, 612
Fallowing, remarks on, 681, 642
Familiar Botany, 60, 64, 100, 117, 133, 148, 165, 195, 209, 211, 230, 252, 294, 404, 501
Farmers by the Kimballs, rev, 189
Farm-dresses for keep, 93, 103, 669; fences, 205; ditto mode of making, 205, 660; stock-keeping, 787; stock, cheapest means of wintering, 613; bailiffs, 201, 205, implements, economical, value of, 693, 695; ditto straight of, 669; yard manures, 661; ditto experiment with, 773 ditto treatment of, 528, 699; labourers boys to employ as, 630; servants in East Lothian, 659
Farms, Advice on the Management of, rev., 93, experimental, 90; small, management of, 389, in Monmouthshire, report on, 821
Farmers' capital 14, 137, 265, 289; Ready Reckoner, by T Skilling, rev, 709, caution to, 142, 174, 222, Club Annual Reports, 769 817, Almanack, &c., noticed, 789, 823; friends on, 764.
Farmers' Club—*See* Societies
Farming, remarks on, 25, a few notes on 788 for Ladies, rev, 453, Scotch 740, profits of, 73, work of 638 and gardening, 101, good, 326, Scotch and English, 742, on the Cotswolds 803; the No pasture system of, 875, Davis's system of, 804, science of, 344
Fastoff Raspberry, 117, 148 669 798
Fatee Gardens near Canton, 590
Favourites of the Flower-Garden, by G. Francis, rev, 590
Fences, 305, destruction of, 820; mode of making, 180, 660
Fence for trees, 660
Fence, Macclesfield, Gardens at, noticed, 28
Ferns fossil, 72, to remove, 68; hybrid, 600
Fertilisers of Commerce, 218; by C. W. Johnson, rev, 246
Festuca elatior, 236
Fever in young cattle, 219
Fever fly, 803
Figs, to cultivate, 5 culture of, 54, 261, 640, barrenness in, 147, remarks on, 184, 200, management of, 228; tree, dwarfed, 503; to manure, 689
Filbert, management of, 856
Fire flies, to naturalise, 262
Fire clay as manure, 693, 756
Fish ponds, tree leaves injurious to 797
Flax cultivation of, 44 124, 197, 218, 232, 251, 267 303, 32, 349, 372 fields, weeds in, 89, as food, 594 610, seed as food, 626, 692, 704, 7 & 780 Essay on, by J Sproule, rev., 228
Fly in sheep to prevent, 756
Florist flowers, intended shows of, 915
Florist's reformed, 872, flowers, Dr Lindley's opinion on, 603, Journal, No 63 rev, 783
Flowers, guano a preservative of, 388
Flower borders, baskets round, 834
Flower gardens, bedded out plants in, 525; appearance of 550 61, to decorate, 617, 705, plants for 656; modern 500
Flower-beds, baskets round, 859
Flower seeds, adv, Hurst and M'Mullen, 130, Sharp, Warner and Warner, 140, Cooper, 194
Fodder for horses, 285, 419
Food for cattle, 153, Gorse as, for horses, 75, 90, 139, 149, 203, 234, Horse chesnuts as, for sheep 305, best spring crops for, 657, flax seed as 594, 610, 676 692, 708, 734, 789, 820, Acorns as, for pigs, 699, 772, Rape for, 878
Foot rot in sheep, 204, remarks on, 506
Forest trees for a chalky soil, 40; to prune, 54, 101, 117, 150, 214, 161, 502, 630, 651, 699, 716, 732 749, 769, 765, 781, 795, 839, 870; for a bleak situation 816, management of, at Nerquis 651, 701, 717, 763, 781; to transplant, 503, 734 781, growth of, 541; M Chevandier's experiments with, 530, quick growing kinds, 544, judicious pruning of, 740, select, 285
Forcing, unseasonable, remarks on, 571
Forks, Dr Yelloly's, 787
Forget me-not, 220
Fortune (Mr), news from, 103, 318, 655, 790
Fossil Ferns, 72
Fountains, 216, remarks on, 797
Fourcroya gigantea, 540, 635
Frames covering for, 797, 798; for Cucumbers, 798, to clear of insects, 869
Freckles remedy for, 560
Frith of Tay, inclosures from, 837
Frost in Dec, depth to which it penetrated the soil, 843
Frost, effect of on Elm roots, 87; on glass, 854
Froth fly, remarks on, 405
Fruits cultivated in Madeira, 736, Syrian, 261, to gather, 687; to preserve, 400, 524, 597, 664
Fruit trees, to dig among, 5, to render independent of the stock, 39, select, 72; adv., Rivers, 50, Forrest, 81; canker in, 49, 662, 624, 767, pruning of, 779; summer pruning of, 502, 503, to root prune, 120, wash for, 181; salt as manure for, 688; Lichens on, 56, 248, to pack for New Zealand, 573; kinds for espaliers, 752; sorts not liable to canker, 708, to plant, 797 list of good sorts, 816, remarks on root pruning, 816
Fruit-tree borders, to crop, 832
Fuchsia seed, to sow, 24, 300; adv, Miller, 28
Fuchsias, select, 120, 196, 200, 432, 624; adv., Epps, 97, Youell, 98, Hancock & Son, 98, Pawley, 161; Rogers, 162; Girling, 177; Smith, 177; Mr. Wood's remarks on, 163, 179, 197 212, 227, 248, 315, 355, soil for, 832; hardy, 477; to graft, 295; to hybridise, 593, 654; to keep over winter, 765, 797
Fullers' earth, agricultural character of, 577; effect of on crops, 773
Functional disease, 180, 214, 246
Furnace, Williams's improved, 179

G

Galls, remarks on, 764
Galvanism, to apply to crops, 598

Thomas Wild, Hon Sec.

MR. TESTIMONIAL. — The Committee for

Promoting this Tribute of Respect to the distinguished, Curator of the Edinburgh Royal Botanic Gardens, beg to state that in consequence of representations from several quarters, they have extended the time for receiving Additional Subscriptions to the 1st of February, by which date they hope that all who wish to join in this object will have communicated their intention to the Treasurer, Mr Wm. Brand, W S , 1, Queen street, Edin., from the number of contributors and amount already received, it is improbable that any further delay will take place , and the Committee would much regret if any friends were overlooked, or should be too late to have their names inserted in the list as finally arranged for publication. Edinburgh, 28th Dec , 1843.

NEW HARDY ANNUAL.

VISCARIA OCULATA—DARK-EYED VISCARIA.

T. and J. BACKHOUSE, Nursery and Seedsmen, York, have the pleasure of offering to the Public the above new and beautiful Annual, which is figured at page 85, (No. 10), of the "Botanical Register," for 1844. The blossoms are of a bright rose colour, with a deep crimson eye, and changing to a pale purple. It flowers very abundantly through the latter part of the summer and autumn. It is a native of Algiers, and may be sown either in the open ground in spring, or raised in pots and planted out.

Packets, 2s. 6d. each, will be sent, on the receipt of a Post-office Order, postage free, to any part of the Kingdom

SPLENDID NEW SEEDLING CINERARIAS.—

[illegible] very choicest sorts of Rose and crimson colours, selected from upwards of [illegible] thousand seedlings of last year, [illegible] with numerous specimens of flowering some of [illegible] immediately healthy, and having [illegible] per dozen, carefully [illegible] Applications [illegible] Post-[illegible] Large [illegible] of [illegible] Bulbs, &c. and [illegible]

FASTOLFF RASPBERRY.

YOUELL and CO. have much pleasure in announcing they have now ready for sending to any part of the United Kingdom, fine Canes of the above highly valuable and much-esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour

IT IS PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, His GRACE THE DUKE OF RUTLAND, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c &c., as well as by the HORTICULTURAL SOCIETY OF LONDON

For further particulars they beg to refer to their Advertisement of the 9th ult Prices as follows —

Packages containing	100 Canes	.	2l. 5s. 0d.
,, ,,	50 ,,	. .	1 5 0
,, ,,	25 ,,	. .	0 14 0

Package included. The usual discount to the Trade, when not less than 200 are ordered

*** Caution.—Y and Co beg to call the attention of their Friends and the Public in general to the fact that they have appointed no Agents in London for the sale of the above, and cannot be held responsible for its being genuine, unless purchased direct from their Nursery

YOUELL'S TOBOLSK RHUBARB, 12s. per dozen. —For particulars of which see their Advertisement of the 18th November

TWO NEW SEEDLING PICOTEES.—"Lady Alice Peel," 10s 6d, and "Mrs. Benyon," 10s 6d per pair —These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, and kindly presented by that gentleman to Messrs Youell and Co, for Particulars of which, see their Advertisement in this Paper of the 16th of Sept.

FINEST CARNATIONS and PICOTEES.

YOUELL and CO. beg to refer the readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation

The selection being left to Youell and Co.

FUCHSIAS.

1 dozen of the newest and very best sorts	21s.
1 dozen fine do.	12s.
1 dozen good show varieties	6s.

Sent by post, free, to any part of the United Kingdom.

ARAUCARIA IMBRICATA.

YOUELL and CO., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms —Fine robust 4-year-old plants, 8 to 9 inches high, 10l per 100, or 30s per dozen —Great Yarmouth Nursery, Jan 4, 1844

THE WALCHEREN CAULIFLOWER.

MESSRS. MARNOCK and MANLEY beg to offer the above valuable article, warranted genuine, at 4s per ounce, sent by post or otherwise, with a Treatise on its management, so that it may be kept in succession, fit for Table, throughout the year. It produces beautiful, large, compact, Lily-white heads, of a most delicious flavour, perfectly hardy, requiring no hand glasses, it not only produces a better quality, but a much larger quantity, on the same space of ground as the old kinds of Cauliflower. It will be quite indispensable both to large and small gardens, for no Gardener, after having once had it *true*, would wish to be without it All kinds of Kitchen Garden, Lawn Grass, choice Imported and other Flower-seeds, warranted to grow freely, and genuine

N B Their Catalogues of Flower seeds, comprising every thing that is new and rare, are ready, and may be had on application.

Nursery, Hackney, Jan 4, 1844

TO GENTLEMEN PLANTING.

J. and J. FAIRBAIRN are induced from the uncertainty upon which they hold the Manor street Nursery (situated contiguous to the Home Nursery, Clapham Rise, where attention will be given to all applications), to effect a Sale of the Stock at as early a period as possible, consequently beg to solicit the attention of Gentlemen and the trade to the large and remarkably healthy and well-grown stock, consisting of fine large Laurels, twice transplanted, of extra growth, Portugal Laurels, very handsome; Green Hollies, of various sizes; Evergreen Privets, fine Standard and Dwarf Roses in great variety, fine standard flowering Thorns, Almonds, Æsculus, Robinias, and other Ornamental Trees, and Evergreen and flowering Shrubs, with a large stock of fine standard and dwarf, trained and untrained Peaches, Nectarines, Apples, Pears, Plums, and Cherries, of the most approved kinds, and of growth rarely equalled; also, a large assortment of Forest Trees, consisting of Limes, Elms, Birch, Beech, Hornbeam, Spanish and Horse Chesnuts, Mountain Ash, Poplars, and Spruce, and Scotch Firs, also a large number of Gooseberries and Currants, of excellent growth, and of the best varieties in cultivation, to all of which J & J. F. respectfully invite the inspection of Gentlemen and Nurserymen, flattering themselves that the general character of the Stock is such as to ensure unqualified satisfaction, and which they are disposed to offer at very moderate prices for cash.

J. & J. F. respectfully beg to call the attention of Gentlemen to their advertisement of Heaths, &c., which has lately appeared in the *Gardeners' Chronicle*. (Oct. 21 and 28.)

Nurseries, Clapham, near London, Jan. 5, 1844.

SEEDS, NEW AND TRUE.

MESSRS. SUTTON and SONS respectfully acquaint those readers of the *Gardeners' Chronicle* who have hitherto honoured them with their commands, that their grounds being situated at considerable distances from each other, and in different soils, they are enabled by strict attention to supply GARDEN SEEDS true to their kinds, and supply Seeds which they know to be new, thereby preventing disappointment in their crops. A great saving of expense will also be effected, and the most improved sorts insured, by purchasing either of the undermentioned collections, which are selected according to Messrs. Sutton's actual knowledge of the comparative merits of each kind.

	£	s.	d.
No 1.—*A complete Collection of new Kitchen-garden Seeds, of very best kinds, being one year's supply for a first-rate establishment*	3	3	0
No. 2.—*A Collection containing all the kinds of the above, but in smaller quantities*	2	2	0
No 3.—*A Complete Collection, in quantities suitable for smaller Families*	1	1	0
No. 4.—100 *Ranunculuses, in 10 fine varieties, by name*	1	1	0
50 *ditto in 50 ditto ditto*	0	15	0

N B.—Parcels delivered free of carriage to London, or to any part of the Great Western Railway within 80 miles of London.

For Gardeners and others who would prefer selecting the kinds of seeds themselves, S & Sons have just published their extensive Catalogue of new Kitchen-garden and Flower Seeds, which will be forwarded immediately, post-paid.

*** Where a reference is given payment need not be made for twelve months, which will afford ample opportunity for proving the excellence of the Seeds.—Reading Nursery, Berks, Jan. 6th

TO NOBLEMEN and GENTLEMEN who are PLANTING or IMPROVING THEIR ESTATES, and to NURSERYMEN.

RICHARD MITTON, Nurseryman, Pontefract, Yorkshire, has now growing in his Nurseries (which are very high and bleak, and from which plants generally thrive) to be disposed of at *reduced prices* a large stock of Healthy, well-rooted, and Transplanted Forest Trees, of all sorts and sizes, especially Larches, 2 to 3 and 3 to 4 feet high Evergreens, Flowering Shrubs, Fruit Trees of all the choicest Sorts, Ornamental Trees of every description Prices on application may be had of goods delivered free at those prices at any Railway Station or Canal Warehouse north of Derby or south of Newcastle on-Tyne.—Pontefract, Dec. 20, 1843.

SHILLING'S EARLY GROTTO PEA.

J. and S. SHILLING have succeeded in raising the above PEA, the Early Frame Pea, impregnated with the Grotto or Oyster Marrow, which they, with confidence, recommend to the Public generally, being quite as early, and more than double the size of any other Pea in cultivation. It is a dwarf, will stand the winter well, and a good bearer; the pods are full long They would particularly recommend it to Gentlemen and Market Gardeners. Price 3s per quart; 16s. per gallon; 12s. per peck, 30s. per half bushel; 2l. 10s. per bushel. Agents, Messrs. Field and Child, 119, Lower Thames-street, London; Messrs. W. and J Noble, 183, Fleet-street; Mr. Kennan, Great Russell-street, Covent Garden; Messrs. Hurst & McMullen, 61, Leadenhall-street; Messrs. Gray, Apothecaries' Hall; Mr. Hose, Kensington —Northwarnborough Nursery, near Odiham, Hants, Jan 5, 1844

THE BRITISH QUEEN and PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above Two Varieties, the merits of which are thus noticed in the Gardeners' Chronicle. "THE BRITISH QUEEN on Saturday, is the best of all kinds, and will drive Knight's Tall Marrow out of the garden." "THE PRINCE ALBERT, which has been cultivated in the Gardens of the Horticultural Society for the season, produced from it for the table ten days earlier than any other variety grown at the same time." Both Varieties are in packages at 2s. 6d. each, at W. J. C.'s Establishment, Nurseries, or the Bedford Conservatory, Covent Garden.

TO GARDENERS.—**BARNES'** Improved Patent **DUPLEX** or Two Prong Hoe, 3s. 6d. Those who intend to obtain their 3s. 6d. additional by every Journal which does it to be superior to anything hitherto made; cutting both ways; warranted first-rate, and constant throughout the season. It took the first cooling prize at Spratsbury, in 1842. Last season, owing to the carriage and duties, C. B. was unable to show it for competition until all the prize-meal shows were over. As this Harrow has not been exhibited in the London Horticultural Society, purchasers will not be required to pay for it, unless it proves satisfactory. References as to its quality can be given to the most respectable Judges. The principal Amateurs who have seen it have already ordered it for Class-showing, &c. Garnet Rakes, 3l. 3s.; Finger in Rings, 10s. 6d. each. The usual discount to the Trade where the goods are ordered.

The following Nurserymen will be able to supply Plants of it in the spring:—Mr. Keynes, Salisbury; Mr. Catleugh, Chelsea; Mrs. Edwards, York, Mr. Harrison, York, and Messrs. Lord and Holliwell, Beverley.—Hessle Road Nursery, Hull, Jan. 1844

EARLY PEAS, &c.—**HENRY D. CORMACK,** Nurseryman, &c., begs to inform the readers of the *Gardeners' Chronicle* that they can be supplied with the following Early and Portable Varieties, viz.: Cormack's Prince Albert, British Queen, and Early Kent Peas; Taylor's Improved Windsor, and Johnson's Wonderful Bean; Manchester Red and Seymour's White Celery, Walker's Long and Hamilton's Cucumber, &c., with every other variety of Horticultural and Agricultural Seeds, at his Wholesale and Retail Seed-Warehouse, 169, Deansgate, Manchester.

J. C. WAITE, Wholesale Seedsman, London, begs to acquaint the Trade generally that he has made a collection, at very great expense, from the finest Stocks in England and other parts of the world, and can warrant the whole of the Seeds genuine, of the first quality, and the present year's growth. The prices are 20 per cent. lower than at any other house in the trade. Six months' credit allowed where a satisfactory reference is given; 5 per cent. deducted for cash. Catalogues to be had on application at his warehouse, No. 4, Bryer-street-hill, Hatton Garden, London.—Jan. 6, 1844.

ROBERT COOPER begs to inform his Friends and the Public that he has published his Catalogue of Choice Flower-Seeds, &c. for 1844, which he can with confidence recommend, most of them having been grown by himself at his Nursery. Catalogues forwarded by post, on application.—Sion Nursery, Croydon, 1st Jan., 1844.

DOUBLE ITALIAN TUBEROSE ROOTS.—The above have just been received from Italy in a sound and healthy condition, and are warranted double, at A. Corbett's, late Mr. Barnes's, Italian Warehouse, 18, Pall Mall. Price 4s. per dozen. Also a choice collection of Orange and Lemon Plants, &c., ranging from two to six feet high, with strong Grafts and Heads, from 5s. to 25s. each. Catalonian and Arabian Jasmines, &c. Lists with prices per Post, &c.

CABOOL MELON, advertised November 18, is all disposed of. John Ross, Gardener, Holme, Cawdor, N.B.

HARDING, Marchand de Bouquets, No. 1, Cliff-ford street, Bond-street.—Wedding-Baskets promptly executed, Bouquets carefully packed for the country, Glass Flower-tubes for Ladies, and Gentlemen's Fancy Basket Bouquet-holders, Vases, Lace-papers, various Works on the Language of Flowers, &c.

Just published, the Farewell to Scotland, "What though I leave thee, Scotland dear," &c., a National Song, written and set by G. T. Harrison, price 2s., as sung by Mr. W. Harrison, of the Theatre Royal, Drury-lane, with enthusiastic applause, the words by John Gray, with a first-rate Frontispiece of Emigrants leaving Scotland, by the celebrated Harrison.

N.B.—A liberal price will be given for choice Cut Bloom. Orders post-paid.

LONDON, EDINBURGH, and DUBLIN LIFE ASSURANCE COMPANY,

No. 3, Charlotte-row, Mansion House; and 26, Chancery-lane, London.

Trustees.

E. Kingsford, Esq. | R. Hill, Esq. | J. Bidden, Esq.

Directors.

Kennett Kingsford, Esq., Chairman.
Benjamin Hill, Esq., Deputy-Chairman.

Alexander Anderson, Esq. | James Hartley, Esq.
John Atkins, Esq. | John M'Gaffie, Esq.
William Riddell, Esq. | John Maclean Lee, Esq.
Augustus F. Brandreth. | J. Marmaduke Rooster, Esq.

Auditors.

E. H. Carman, Esq. | Robert E. Alison, Esq.

Medical Adviser.—Marshall Hall, M.D., F.R.S., L. and E.

Solicitors.—Messrs. Palmer, Brenan, and Palmer.

THIS IS THE ONLY COMPANY who are bound by their deed of constitution not to dispute any policy, unless they can prove that it was obtained by fraudulent misrepresentations; and numerous cases have shown how worthless may be a Policy obtained from the most influential office, which is unrestrained by this equitable principle, which removes all anxiety as to future disputed obligations, and enhances immeasurably the value of the Policies as documents of security.

THIS IS THE ONLY COMPANY who give to the assured on the above principle the whole of the mutual accumulations, and thus guarantee the same secured.

THIS IS THE ONLY COMPANY who bind themselves to pay the claims in the Policies, although the debts for which they were effected shall have been liquidated before the claims arise.

THIS IS ALMOST THE ONLY COMPANY who grant in favour of Policies which secure, whereby the debt is secured, although the debtor should go beyond the limits of Europe.

The premiums, calculated according to the Carlisle tables, are lower than usual upon young lives, where participation in profits is not required; and for short assurances, which at the expiration of the secured may be continued for life, the rates are as low as can be regard to complete security will permit.

Triennial Accruing Bonus to assure £100.

Age	Five Years	Second 5 Years.	Third 5 Years.	Fourth 5 Years.	Remainder of Life.
20	£1 2 7	£1 3 9	£1 18 11	£2 4 1	£2 16 8
30	1 9 6	1 10 4	2 2 2	2 10 6	3 5 9
40	2 1 6	2 14 10	3 6 3	4 2 5	4 18 4
50	3 11 1	4 10 3	4 10 5	5 10 1	7 9 9
60	5 2 11	5 17 4	7 5 9	8 14 3	10 1 7

THE ONE HALF-PREMIUM PLAN only one-half of the first seven annual premiums is required, the other half being payable at the commencement of the eighth; thus assuring a Policy to the continued for seven years, at one-half of the usual rate, it to be stopped at one-half of the usual quantity; and enabling the assured, seven years hence, when, then of health may prevent them obtaining a new assurance, to continue a Policy at seats of premiums applicable to the age seven years younger.

Prospectuses and Schedules are forwarded to applicants, free of expense, by the manager and agents.

ALEX. ROBERTSON, Manager.

AUSTRALASIAN COLONIAL and GENERAL LIFE ASSURANCE and ANNUITY COMPANY, 126, Bishopsgate-street, Corner of Threadneedle.

Capital £1,000,000, in 50,000 Shares.

Directors.

E. Barnard, Esq., F.R.S. | Gideon Colquhoun, Esq.
Robert Brooks, Esq. | C. E. Mangles, Esq.
Henry Buckle, Esq. | Richard Onslow, Esq.
John Henry Capper, Esq. | William Walker, Esq.

BANKERS.—Union Bank of London.

COLONIAL BANKERS.—The Bank of Australasia (incorporated by Royal Charter, 1835), No. 2, Moorgate-street.

PHYSICIAN.—Patrick Stuart, Esq., M.D., No. 62, Guildford-st.

SECRETARY.—Edward Ryley, Esq.

ASSURANCES may be effected with this Company at reasonably favourable rates, affording every variety of accommodation to the Assured. Participation in Profits, ascending and descending scales of premium, permission to remain one-third of the premium, which is charged as a debt against the policy, tables for the assurance of a sum payable in the event of death to the executors of the Assured, or to himself upon the attainment of the ages of 45, 50, or 60.

To EMIGRANTS to the AUSTRALASIAN COLONIES assured for the whole life, this Company offers the advantages of permission to proceed to, to reside in, and to return from those colonies without extra premium, and to pay their premiums there.

All questions relating to Assurance and Annuities, addressed to the Secretary, will receive immediate attention.

ACHILLES BRITISH and FOREIGN LIFE ASSURANCE ASSOCIATION, 46, Moorgate-street.

Loans granted to policy holders.

Every description of Life Assurance may be effected upon a moderate scale of premium, either with or without participation in profits.

Endowments for children or widows, and Immediate or Deferred Annuities, granted upon fair and equitable terms.

Loans may be obtained on personal or other security by individuals assuring their lives with this Association.

Risks taken on the Lives of Master Mariners and Passengers by sea, either for the whole term of life, or for the voyage.

EDWARD GILBERTSON, Secretary.

Prospectuses and every other information may be obtained by applying at the Offices, 46, Moorgate-street, City.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. Bailey also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. Bailey were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

THE CONICAL HOT-WATER BOILERS, invented by J. Roberts, Esq., may be obtained of any else from JOHN SHEWEN, Ironmonger, &c., Sevenoaks, Kent.

J. Shewen having had every opportunity afforded him by an extensive practice to bring this Apparatus to perfection, begs to offer it as most efficient and economical it may be seen at Messrs. Chandler & Sons' Nursery, Vauxhall; Messrs. Loddiges', Hackney; Messrs. Henderson's, Pine Apple-place; Messrs. Veitch and Son's, Exeter; Mr Pontey's, Plymouth; the Royal Botanical Society's Gardens, Regent's Park; and at the Gardens of the Horticultural Society of London. Considerable improvements have been effected since last season; particulars of which are in course of preparation.

BENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON and CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks which are ornamental in appearance can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of Iron will be found cheaper than of any other material. Mr. Rundle of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

A COMPANION TO THE PEERAGE AND BARONETAGE.
Now ready, Parts I and II. (to be completed in Four Parts, price 10s. 6d. each), of Mr Burke's

HISTORY OF THE LANDED GENTRY; A GENEALOGICAL AND HERALDIC DICTIONARY of the Whole of the Landed Gentry, or Untitled Aristocracy of England, Scotland, and Ireland, to be completed in a single volume, of 1600 pages, beautifully printed in double columns uniformly with the Author's popular

"Peerage and Baronetage."

THE subject of WARD'S CASES having been again brought into notice by the Horticultural Society, who have offered certain prizes for cases of that description next year, it seems fashionable to make a few remarks upon them in addition to what has been stated on former occasions.

Mr. Ward's pamphlet* contains, indeed, all the information that can be given; but it is in few hands, and everybody does not understand the principles on which his cases are constructed. It is imagined by uninformed persons that entire exclusion of air is the great object which Mr. Ward sought to secure by his contrivance. But we need hardly tell the reader who knows anything of the atmosphere, that such an effect cannot be attained by a Ward's apparatus: the air finds its way into every place not hermetically sealed, and such contrivances as close-glasing, puttying, and so forth, cannot exclude it. What Mr. Ward sought to gain was uniform moisture and an exclusion of soot; and these he effectually secured. It is the dryness of the air that destroys plants in sitting-rooms and great towns, and not impurities in the gaseous constituents of the atmosphere, the importance of which has been singularly overrated. By inclosing plants in tightly-

glassed cases light is admitted, soot is excluded, and any desired amount of moisture is securable.

There are, however, some practical difficulties in the way of growing plants in close moist cases, which Amateurs unacquainted with the nature of plants are unable to overcome, but which a sensible gardener, who does not belong to the "drowsy" school, would easily remove; and with a view to the accomplishment of this, Ward's Cases were admitted to the Exhibitions of the Horticultural Society. Among these difficulties, the principal is the adjustment of the amount of moisture to which a plant is exposed in one of the cases, to the surrounding heat and to its own proper nature. Another is the prevention of dew upon the inside of the glass, by which the interior is often entirely hidden. These are practical difficulties, that must exercise the ingenuity of cultivators. Upon the former we can give no information, because each species requires a special consideration. As to the deposit of dew upon the glasses we may observe, that since this is owing to the inside of the case being colder than the air that surrounds it, the only course to take is either to warm the internal air by some means, or to open a door in the case for a short time; and as the latter is the most easy, and is quite efficient, it will be the more generally adopted. Opening the door is an advantage rather than a disadvantage to the plants, if not continued too long.

The reason why these ingenious contrivances have not been more generally adopted, is owing, we conceive, partly to the difficulty of managing them and partly to the Ward's cases which are sold in the shops being remarkably ugly. The former difficulty will, we trust, be removed by degrees, when gardeners turn their attention seriously to it. In order to assist in diminishing the opposition which arises out of the unelegant appearance of the cases, we subjoin the accompanying designs, which any ingenious workman can readily execute either in brass, or bronze, or iron. The chapter of the two-thirds standing legs, the other

* On the Growth of Plants in closely-glazed Cases, by N. B. Ward, 8vo., 1842.

IT is of no use now to ask, how many years it takes to procure those GREAT FERNS, in the mere existence of which men would not believe; it is of no use to inquire how much they cost; it is idle to make calculations any longer as to the average number of pounds of fruit which a dozen square yards of Pine-soil will produce, or to assert that 20 Pines, of 3 lbs. each, are just as good as 10, of 6 lbs.—an argument worthy of a market-gardener, and of no one else. The data on which such reasoners have been standing is knocked from under them; for Mr. Barnes, one of the most successful, sensible, and experienced of modern gardeners, has publicly explained his mode of proceeding, and shewn, that with no more expense, trouble, or trouble—on the contrary, with less of all, but with a good deal more skill and common sense, all the incredibilities, which we have been blamed by the stand-still gardeners for making public, are attainable.

He has shown, too, other things. He has not only exposed the folly of the doubters and speculators and cavillers, of whom we have lately heard so much, but he has completely confirmed the justice of our assertions, that we are only on the eve of discovering the true mode of Pine-growing, and that in the cultivation of the Pine we have a most striking illustration at once of the value of charcoal, and of the one-shift system, advocated by Mr. Wood.

Although we do not feel ourselves at all called upon to pay attention to the foolish distinction drawn by uninformed persons between what they are pleased to call theory and practice, yet, on this occasion, it may be as well to remind them that Mr. Barnes, of Bicton, is, in the strictest sense of the word, a practical man—a very sensible one, no doubt; but such an intelligent practical man as you will find many of, all over the country: not, indeed, among those practical men, who, as he says, "lie in bed half the day, and walk about the other half with their hands in their pockets" (p. 696); but a gardener full of zeal and knowledge, who has followed his calling for more than 30 years, self-taught, aware of his own deficiencies, as all men of sense are, no trumpeter of his own merits, great as they are, but hard-headed, hard-headed, earnest, and industrious; relying on his own resources, and not, like the countryman in the fable, crying out to Jupiter to help him out of the heavy road into which he may have driven his cart. In short, he is not one of those fine gentlemen who lay the blame on their men, or anything rather than themselves, for the mischief that arises out of their own incompetence, but exactly what a good gardener always is. Such is the man whose statements respecting the Pine-apple we are now about to quote in favour of our own views of what the system ought to be. The account to which we refer is in the "Gardeners' Magazine," just published, and which we regret to announce the termination. The most essential points appear to be the following, in addition to what *good* Pine-growers already practise.

There is no disrooting. However men could have fancied that the best way of making a Pine plant grow is to cut off its roots, it does, pass our ability to imagine. Mr. Barnes most properly exposes *that* folly.

"I know it is considered by many practical men that the Pine-plant is an annual-rooted plant, and that it requires disrooting in the spring; practice has convinced me of the contrary; but unnatural treatment too often causes it to lose its roots, not only annually but several times in the course of the year. It is stated by others that it is impossible to grow or cultivate fine beautiful fruit in some localities, for the want of proper soil; I am perfectly convinced that the obstacle is not so much the want of proper soil as the want of knowing what proper soil is, how to get it healthy, and how to keep it healthy." In fact disrooting a plant is like drawing a man's teeth in order to make him eat.

Soil, again, has been looked upon as a great question. The French swear by peat, the English by loam, the South Americans by sea-sand. But, says Mr. Barnes, —"Practice and observation have taught me that fine Pine-apple may be produced to very superior perfection in any locality, and that any soil that will produce tolerably good Wheat will grow good Pine-apples, and so will soil that will produce nothing but stunted Furze-bushes, Brambles, and short-starved Heath. The defect is in the means employed in getting it to a healthy pure condition, and keeping it so with heat, light, and water, all pure and acting together. We have no bad soil in this country; it is our ignorance makes us think so. How often do we hear men remark, on observing plants, [illegible] neighbour's opposite to their own, [illegible] convenience, spite, &c., I could grow [illegible] how familiar these remarks are to [illegible] step, constantly, to get the soil which [illegible] gets his from; but without making [illegible] confident there will still be disappointment. [illegible] idea is, that the soil is the stomach of [illegible] without the stomach is in a pure and [illegible]

...ture, and means applied to keep it in that condition, how can we expect vegetation to thrive and continue vigorous and healthy? The soil I have made use of these last three years is *from a hungry situation on a common, where some poor, starved, stunted Furze-bushes grow from 4 in. to 8 in. high*, and some Heath and stunted Brambles here and there; the subsoil a rank red clay; *I do not know where to look for soil that to all appearance is poorer.* My system is to cut the surface about 2in. or 3in. in thickness, with a mattock, in sods, or turfs, as it is termed in some places, with bushes and whatever vegetation there should happen to be growing on it besides, in dry weather in summer; taking it home, and stacking it snugly together, without adding the least particle of manure or anything else whatever. I make use of it *in as rough a state as possible*, Furze bushes and all, without anything whatever being added, only preferring it to lie together a sufficient time to kill the vegetation, that it may not become troublesome by growing amongst the plants, and never by any means making use of it when rotted down, I would sooner use it quite fresh and green. *My reason for using it in a rough state, and without being decayed to any extent, is that the atmosphere, heat, and water, may have an opportunity of acting* in unison with the salts, limes, &c., of the earth, and good drainage and some coarse charcoal on the top supply the means of all acting together in the healthiest manner."

We beg the reader to pay particular attention to these directions, and especially to compare them with what Mr. Wood is always insisting upon, viz, the indispensable necessity of a coarse permeable soil We will also ask him to compare them with the common directions to grow plants in *finely sifted* soil. Comment is at present unnecessary.

We shall resume this subject next week.

ROT IN LARCH.

In the *Chronicle* of the 2d Dec, p. 842, I find Mr. Wighton, in his observations on the rot in Larch, inclined to attribute that disease to an excessive, or over rampant, growth of the plant when young, and not, as is generally supposed, to the nature of the soils in which it grows. If, indeed, Mr. Wighton could prove that the growth of the Larch when young, upon soils where the disease shows itself at an earlier or later period, was invariably of the rapid description he insinuates, or that in such cases it was quicker, or even equal to that of the trees where it perfects its heart-wood, and shows no signs of decay up to an advanced age, then I confess his hypothesis might appear plausible, and to have some foundation in fact. My own experience, however, which extends over a period of nearly 40 years, during which I have been a planter of the Larch to a considerable extent, and upon a variety of soils, leads to a different conclusion, and convinces me that the disease is to be attributed entirely to the nature of the soil in which it grows; but whether to an excess of various constituents in such soils, or to a deficiency of some peculiar quality necessary to give perfect maturity to the wood, that is, bring it to the state known as sound heart-wood, still remains a matter for further investigation; and perhaps is only to be found by a strict chemical analysis of these rot-producing soils.

That the growth of the Larch upon land subject to produce the rot is always of the rapid description assumed by Mr. Wighton is certainly not the case; on the contrary, where the disease appears at an early period, say when the trees are from 12 to 14 years old, their growth is comparatively slow from the time of their being planted; and the unsuitableness of such land for the production of such timber is at once apparent, even upon soils less deleterious, where the disease makes slower progress, and does not show itself prominently till a later period, the annual shoots of the trees when young at seldom equal, either in point of strength or length, to those of healthy Larch in the circumstances antagonist to its habit, where it lives to attain maturity, and produces that rich-looking and valuable timber for which it is celebrated. Neither can I assent to Mr. Wighton's assertion, that the best and most durable Larch wood is that produced by trees of the slowest growth, and upon poor soils, on the contrary, I find that the finest specimens of Larch timber are the produce of trees not only of the largest dimensions, but of such as have grown rapidly, and luxuriantly from their earliest years up to an advanced age. At Dunkeld and other parts of the Scottish Highlands, where the finest Larch timber is produced, it might be supposed from what Mr. Wighton says, that there the trees were of tardy growth; but let any one go and examine the noble Larches which shoot up in towering spires in the deep glens and mountain declivities of that interesting and romantic country, and measuring their age, them say that their growth has been slow, or inferior to that of the Larch in rot-producing soils. Neither can the soil at Dunkeld, and other Highland districts, be deemed of the poor description mentioned by Mr. Wighton; on the contrary, it is in many places deep and good; not that it contains much vegetable matter or manure, but is composed of the disintegrated debris and debris of the older series, which in more respects to the habits of the Larch and others of the Coniferæ forms favourites of a more humid period. In respect to the trees in Tweed, I know that the finest trees producing valuable timber grow upon ground of good quality, provided it be not immediately incumbent on cretaceous or basaltic formation. In a deep dene or glen, where the rock is one of the lower mountain or mountain limestones, many Larches, though not more than 47 years old, have attained a height of 80 feet and upwards, and a circumference of bole, at two feet from the ground, of nearly six feet. Of two trees (by no means the largest in the dene), cut down about a fortnight ago, the length of one was found to be nearly 60 feet—of the other, about 73. The sap-wood was not more than three inches thick, the rest being heart-wood, of a rich colour and excellent quality. When squared and sawn up, planks of 18 feet in length and a foot in width were obtained from the butends. It is almost unnecessary to add, that these trees had grown at a rapid rate from the time they were first planted, much more so than others upon ground where the taint begins to show itself when they reach their 15th or 20th year. In the "History of British Forest Trees," published by J. Van Voorst, an enumeration of the different descriptions of soil in which the Larch is liable to the heart-rot is given, drawn as well from the observations of Mr. Matthew, as from those of the author himself. Upon such it would be in vain to plant the Larch in the expectation of obtaining large and sound timber, nevertheless I still advocate its liberal insertion in plantations upon such soils, as it is, even under these circumstances, the most profitable temporary occupant that can be planted, affording at the various thinnings, a supply of valuable material for minor purposes, provided it be taken down before the disease has advanced too far. In conclusion, I would say, let not the planter (provided his ground be sound, that is suitable to the habit of the tree) be at all alarmed at Mr. Wighton's declaration, that a rapid growth of his Larch is only laying the foundation of useless timber.—*P. J. Selby.*

THE SEEDS OF GARDENING.—No. I.

Of all the systems by which plants are obtained there is none so beautiful or so perfect as their development from seeds; yet, assuredly, none so much neglected, I might say despised, as this primeval plan of propagating. The exquisite delicacy of the workmanship that folds the future plant in the small cell of the seed must be evident to all, the globular form that many seeds take, and the general contour and character of all, show how admirably the seed is adapted to transport the species and secure its welfare.

The extent to which certain valuable plants may be increased by merely depositing seeds in the earth without further care or trouble, is truly marvellous; witness the vast forests of Fir-trees from seeds strewn on the mountain, and the fields of yellow Corn from grain scattered on the fallow ground; and at this season of the year, when the Yew-trees are laden with their rosy fruit—the inglorious prey of the greedy mouse and undomesticated fowl, the unbroken sunbeam, and the hurricane unchecked pass over the treeless strath and lone hill side, where the only shelter is a fox's cave, and the only shadow that of some ruthless crag. And how little of human aid is wanted to enable the Yew, that truly British evergreen tree, to extend itself by thousands in such situations, at no expense save the labour of the patriotic hand that strews the high ground with a basket of Yew-berries! and though years must elapse ere this verdure arise, yet, assuredly, it would come, and that not for a season or an age, but for a thousand years. If your readers would only look over their Yew-trees whilst the twigs are yet laden with their rosy-cupped seeds, requiring no further culture than a clear space of earth as large as the nail of the finger that deposits them, I think many would be induced to remove the beautiful germ of the Yew-tree, with its ruddy chalice, to a spot where it might dwell and become the parent of myriads, to the credit of the hand that gave it place, and the landscape which it and its progeny would adorn.

These, and thousands of other familiar examples, might be mentioned to show the immense importance that a right method of saving, preserving, and distributing seeds would be to mankind in general, and to gardeners in particular, whose livings mainly depend upon plants of which seeds are the primary stock. I flatter myself, therefore, that the time is come when neatness, order, and system, may, and indeed must be, introduced into the seed department of gardening, lest Chaos should come again; for if we average two thousand as the number of species cultivated in a modern garden of moderate extent, and conclude that one-half of these are either produced or producible from seeds, we have a thousand separate moieties of plants in the germ to preserve from injury, arrange in order, and distribute with judgment, in time and place appropriate to their welfare and the wants of a family.

The coatings of most seeds, or, in other words, the inner packing-cases, assigned them by nature, are for the most part air-tight; and we frequently find the germs sealed up as it were in little bags or husks, in a sort of membrane, containing ingredients more or less soluble in water. Hence the necessity of keeping such seeds free from damp till they are wanted to germinate; yet it must equally be borne in mind that excessive dryness proves injurious to the vitality of seeds; for when the oily or glutinous matter in the coating of the seed gets dispersed, or drunk up by heat and dryness, the inclosed germ can no more live in that arid atmosphere, than a plant plucked up by the roots could live exposed to the heat and drought of sun and wind.

Now, although plants might, and indeed often do, endure exposure to the air, &c. in transplanting, and survive the check, yet the infant germ, a slight of its mantle, or of that property which made its coating weather-proof, soon shrivels, and after a time quite perishes, and decomposes in mischance "a day lower." When seeds are quite ripe, they can generally in a greater or less degree as they can be kept perfect; for the germ of ripe seeds being superior to new ones, and such-like theories, are now pretty nearly exploded. Indeed, new seeds are found to resemble new eggs so much, that the systems resorted to by cunning housewives when eggs are cheap, to keep them sound till the price rise, are excellent and simple illustrations of the principles of preserving seeds. Eggs immersed in lime, or smeared with butter, and the cask in which they are packed occasionally turned to keep the yolk from settling, will preserve eggs marketable for many a day.

Now seeds of the Brassica tribe, of which more than one sort can hardly be saved in the same garden unadulterated in any one year, require some pains to preserve them, and a very simple and effectual method of doing this is to rub off their outer coats by giving them a good shaking in a rough woollen bag made slightly greasy with oil of Turnip-seed or suet oil; this operation being to them a regular brushing and polishing, not only preserves the seed, but brightens the sample and makes it more marketable and sleek in the coat, which sleekness, it is well known, is one of the tests of new and fine seeds—the coating of lime by excluding air and preserving uniformity of temperature and dryness, is perhaps the simplest safeguard that could be used in the sound keeping of seeds.—*A. Forsyth, Alton Towers.*

(To be continued.)

DR. THACKERAY'S WELCH PLANTATIONS.

The following authentic account of the places where Dr. Thackeray's plantations have been made will interest every one who has an opportunity of visiting North Wales. We hope to be soon able to lay before our readers a full account of the system of management observed in them. In the meanwhile we may state that nearly 3000 beautiful Oaks of five years' growth have been this autumn transferred from Dr. Thackeray's nurseries to vacancies in the woods, and that all boughs are left in the plantations for the poor, who carry them away.

Those plantations marked with a * in the counties of Denbigh and Flint, and Wenmait, in Merioneth, belong to Dr. Thackeray.

TURF ROASTING.

About two years ago, when conversing with a cultivator respecting the best compost for China and other Roses in pots, he mentioned that he had found thin parings of turf dried in the sun in summer, so as to kill the roots of the grass, a most excellent compost. I tried to bear this in mind as an excellent hint, but in the hurry of business it escaped my memory till the commencement of this summer of 1843, when, owing to the continual wet weather, I found myself unable to carry out the idea; drying the turves in an oven then occurred to me, but this happened to be inconvenient; a temporary furnace then struck me as being an efficient method, and this I quickly made by placing some loose bricks into three sides of a square about two feet in diameter and 18 inches high, leaving one side open for the admission of fuel: on the bricks I laid a stout piece of sheet-iron, so as to form a kiln, under this I made a brisk fire with wood, and then commenced kiln-drying. My pieces of turf, which were one inch or a little more in thickness, and about a foot in diameter, were suffered to remain in my temporary kiln nearly two hours, during which time they were turned several times: by this operation they were slightly blackened and charred on both sides, and every fibrous root completely killed; the turves were taken hot from the kiln, immediately chopped into pieces, from half an inch to an inch in diameter, mixed with an equal quantity of rotten dung, and used for potting Roses, with pleasing results; for their roots in a very short time pervaded every part of the compost, and the plants assumed a healthy and vigorous aspect; the drainage is also quick and complete, contributing in no small degree to the well-doing of the plants.

I need not point out to the cultivator the advantages of this simple process in destroying grubs, wire-worms, and grub that so often infest the fibrous roots of plants, the method and economy left to being, and the [illegible]

...may be supported with four-inch iron work, say from three to four feet in diameter, the height need not be more than eighteen inches, and bone flat bars of iron may be placed across to support the sheet of iron; this will form a kiln of sufficient size to roast a large quantity of turf. I have reason to believe that turf, even from the most retentive soils, will be rendered by fire-heat thus applied, light and porous, and fit for pot-compost for most plants. —*T. Rivers, Jun.*

BEES.—No. I.

"Bees," says Cobbett, "are of great use in a house, on account of the honey, the wax, and the swarms that they produce; they cost nothing to keep, and want nothing but a little care." If there is anything more profitable to the gardener or cottager, and one to be more easily managed by him than a few swarms of Bees, all that I can say is I have never seen that thing. All men, especially those of narrow incomes, should principally endeavour to gain a knowledge of those things which particularly concern their well-being. The gardener—to whom I address my remarks—cannot, I assert with confidence, dispose of an hour or two a week in a more lucrative way than in managing an apiary. Whilst the gardener is being taught how to make 10*l.* a year on an average of his Bees, the amateur too, I trust, will learn how to obtain a plentiful supply of honey and honeycomb. The only objection that can be raised to the keeping of Bees is that they extract the quintessence of flowers, and thereby impoverish or rather lessen the quantity of butter. I know an old parsimonious farmer who was so fully convinced that Bees impoverished his fields, that he trod to death all that he could put his feet on. However, it is questionable whether Bees do diminish the quantity of butter; indeed, there are only one or two flowers which cows eat that Bees collect honey from. [This old farmer was a monstrous blockhead.]

Though Bees can be managed properly without a knowledge of the conformation of their heads, trunks, and abdomens; yet it is indispensably necessary to know some of their habits, or points connected with their history, which I shall now notice. In almost every hive there are at certain seasons of the year a queen or female, drones, males, and neuters, or Bees without sex. A queen-bee is 14 days in being hatched—takes the drone on from the first to the fifth day after she is hatched—begins to lay on the 10th day from the time she is fecundated—lives four years, generally speaking—and is, as her name implies, monarch of the hive. Neuters, or working Bees, are 21 days in being hatched—do all the drudgery of the hive—are loyal subjects, but have neither an hereditary nor an absolute monarchy—and are miserable, and work but little when they have not a queen either reigning or in embryo. Bees'-eggs are transmutable; that is to say, either females, males, or neuters may be obtained from them at the option of the apiarian.

The Hives.—What I lately said on the superiority of large hives is, I am sure, more than sufficient to induce all bee-masters to keep their Bees in large hives; but as some say that once calling does not always awake sleepy men, and as I am anxious that this small treatise should be complete in itself, I shall here show, in the clearest way possible, that large hives are superior to small ones. Oh that Bee-book authors would use their reasoning powers or try experiments in order to find out how large hives ought to be! No person will ever pretend to say that a Queen-Bee can lay and cause to lay when she likes, or that she has control over the number of her eggs. Very well. Let us show with one or two simple experiments that by keeping Bees in small hives you force them to destroy two thirds of the eggs which queens lay. Select three hives full of combs and Bees, take the queens from two of them, place one above another, shut the mouths of the upper two, which will compel the Bees to pass through holes (six inches in diameter); cut out off the crowns of the middle and undermost hives, and you will find that the combs of the three hives will be as well filled with brood as they were before from the eggs of three queens. An equally decisive experiment is to exchange the queens of a small and a large hive. If a queen be taken from a hive containing 9 superficial feet of comb, and put into one containing 27ft., and the queen of the hive containing 27ft. put into that containing 9ft., you will find that the combs of the large one will be as well filled with brood as they were before the change took place. "According to Huber," says Dr. Bevan, at page 41 of the "Honey Bee," "a queen ordinarily lays about 12,000 eggs in two months, but," continues this celebrated author, "it is not to be supposed that she lays at the rate of 12,000 eggs every two months; she does so at the principal laying, in April and May." If the Bee-master would be at the trouble of putting a swarm or two [illegible], weighing 8lbs. or 9lbs., with a queen that has finished her "principal laying," into a hive containing 24 superficial feet of comb, he would find at the end of [illegible] above 20,000 eggs set. At page 124 he says—"Whatever advantage the putting of two swarms into a hive may give to the family during the first year of its [illegible], it can present none beyond that period; for the [illegible] that were introduced will have paid the debt of nature before its expiration, and are thereby reduced to a level with those that were not doubled." *Dr. Bevan* is wrong here, for a swarm that weighs 8lbs. hatches double the [illegible] that weighs 4lbs., and consequently [illegible] of Bees will live throughout the [illegible] that quantity of eggs in the spring, and [illegible] begins with [illegible] hives [illegible] [illegible] [illegible]

…stalk double-flower, wall coloured, and as perfect as if …ed in July, being the eighth month …ming it has been in bloom in the open air. …the next four months they will be in flower under …, so that there is little difficulty in having them in …ence throughout the whole year.—The following were …ming in the garden of G. Innes, Esq., Bowater Cres…, Woolwich, on the 29th of December, viz.:—

Another correspondent informs us that there is at …ndon, the seat of N. Hibbert, Esq., near Watford, …ts, a Camellia of the old double striped variety, having …ir fully expanded blooms, and more ready to open. It …growing on an open wall, and except being situated near …-angle of a wall with a south-west aspect, it has had no …r protection from the frosts that have already visited …t district.——Mr. Ross writes from *Inverness* as fol…:—We were compelled last week to cut the Grass …, which was softer than in September. Cauliflower-…s in front of a wall have been growing rapidly for …t five weeks. The herbaceous plants are springing …. Stocks produced buds to flower this winter. …mpanula is in bloom next the wall. Maurandyas, …, Petunias, are quite green. Rhodochiton is in …r. Cobæa scandens produced shoots two feet long …ly. All the Verbenas that were left out are quite …, and some in flower. The congregation of the …church of Cawdor was sitting in the open air till last …, when they got into a wooden erection, 63 ft. by …. They felt but little colder, as the oldest of them said …never saw such a mild winter.

Foreign Correspondence.

Paris, Dec., 1843.—As the subject of PINE GROWING …s just now to attract much attention in England, …e the result of my observations upon the culture of …in France may be of service to some of your readers, …ularly as I have had the opportunity of seeing the dif…modes of pot and open ground culture upon a large …in all stages and seasons, not only in Paris, Versailles, …ndon, but also in the northern and western depart…. The time was when 11 and 21bs. were considered …good size for a Queen, and 4lbs. for a Providence; but, …to the improvements in science, hot-water, and open …culture, a new era has commenced, and the Pine-…is effecting as great a revolution in his department …the Horticultural amateur has accomplished with Pelar…, Roses, or Dahlias. As the Potager, or King's …Garden, at Versailles, is the largest establishment …kind in this country, and moreover, has the honour …been the first in passing the rubicon of customary …, I cannot do better than detail the mode of cultiva… and varieties most esteemed. This garden was laid …by "Le Quintinie," in the time of Louis XIV., and …nothing was spared to render it a worthy appendage …the palace of Versailles, which was then the residence …the gayest Court in Europe. The present distribution …the fruit-garden retains a great similarity to the plans …Quintinie, in 1681, with the exception of the forcing …ment, which at that time consisted only of a few …s for Melons, Cucumbers, and small Salads. It …not till about the year 1702 that the Pine-apple was …duced into the Potager, and so little was then known …its culture, that no mention is made of any fruit having …been obtained till 30 years after; in fact, this and other …fruits do not appear to have received much atten… until the time of the Empire; since the peace still …greater improvements have been made; many new houses, …specially for Pines, have been erected, and the hot-water …is all but entirely adopted. The honour to which …has attained is more particularly due to M. Massey, …present director of the Royal Gardens, and to the …ener in the forcing department, M. Grison, who …during the last few years, so successfully introduced …ench ground system of culture. The whole of the …ation-pits and fruiting-houses are now heated by hot-…, and has been entirely discarded; all the water-pipes …, some round, others quite, quarters, 5 or 6 …s wide, by 3 deep, like those in use at the Hon. R. …'s, at Roswell; these last are now becoming very general …bottom-heat. In England I believe almost all the …for warming the atmosphere are round—hair, pa…ornary, the greater part are flat and upright, from 6 …to 9 inches high and 4 inch-think; in these the water is …ly circulates quite so freely; and moreover a great …is gained by the comparatively short time in …a sufficient degree of heat may be obtained, the dif…being almost three to four, on the contrary, how…is not quite so rapidly. The pathes, of which I have seen only three different materials, viz. 2d, of a form totally unlike them, must be employed; these are cubical, and the makers with whom I have conversed in Paris appear to think that form are very superior to theirs. The soils used in England and France for Pines are altogether different; in almost every Stoney that I have seen in England, a strong loamy soil was predominant; at Paris, Versailles, and I understand at almost every other place in France, they are now grown in peat; some persons have tried loam and leaf-mould, others loam and peat, or common earth and black sand, but none of these composts have proved satisfactory; nevertheless, many eminent Horticulturists, and among them M. Poiteau, the editor of the "Bon Jardinier," still think that a stronger soil would be better suited to the end in view: not so, however, the actual growers; the universal opinion among them is, that pure peat is for every variety the best adapted to insure a rapid growth, which they consider so essentially necessary to obtain large fruit; and certainly the health and vigour of the plants, and the enormous fruit which has been obtained in this soil would lead you to believe their opinion well founded. The treatment of the plants when young, and indeed throughout all their stages in pots (with the exception of soil), is very much the same as in England; it is therefore to the advantages of the open-ground culture that I would direct the attention of English growers. The suckers are planted in August and September, and remain till May in pits of the lowest temperature, when frames for the summer are prepared of dung and Chesnut or Oak leaves, well mixed and sweetened, of four feet thickness, which is found to retain a steady bottom-heat of 18° to 20° of Réaumur (72° to 75° Fahr.) for a much longer time than from dung alone; upon this is a bed of peat (sometimes mixed with a few decayed leaves and black sand), about eight inches deep, in which the young plants are set at sufficient distance apart to allow for six months' growth. These frames are well protected by straw mats at night, and as the summer advances air is liberally given, and water as occasion may require. Rapid progress under this treatment is soon apparent; here they remain till the end of September or middle of October, when they are once more repotted in 24s or 16s in pure peat, and placed in the winter pits with a bottom-heat of 22° to 25° of Réaumur (82° to 88° Fahr.), while the atmosphere ranges from 15° to 17° (82° to 86° Fahr.) In the following May those which are to fruit in pots are shifted into 16s or 12s, while those for the open ground are planted in the fruiting-houses, the soil of which is pure peat 9 or 10 inches deep; the bottom-heat is now increased to 25°, and the air never below 17° or 18°; in September and October many of the plants are showing fruit, which comes to maturity in time for the Paris season, which commences in December. Such is a brief outline of the open ground system, as practised at Versailles and elsewhere. This treatment has not, however, been found equally advantageous to every kind of fruit; it is only in the Cayenne, Enville, Jamaica, Providence, and one or two other varieties, that the increase of size has been most apparent; very little difference has been perceptible in the size of the Queens (at least at the Potager) and by far the greater number of this kind are still grown in pots. There are at this time some splendid specimens of the larger kinds in the open ground, especially among the Cayenne Lis; some short time ago I noticed two magnificent fruits of this variety on two-year old plants; they were in every respect perfect models of form, and must have weighed, I think, upwards of 12 lbs. each. I measured one, which was 11½ins. long, by 8ins. wide. These are not solitary instances of the advantages of this system, for I have before seen others of equal magnitude and beauty; while fruit of the same variety in pots has not weighed more than 5lbs. or 6lbs.; similar results have attended the Enville and Providence, of which there are some almost, if not quite, as large. These two last have been hitherto extensively grown on account of their weight; but the irregularity of form in the Enville, and secondary quality of the Providence, will now no longer permit them to retain the place they have hitherto done, neither of them being at all comparable, either in form, size, or flavour, to the Cayenne Lis, or Epineux, which are second only in delicacy of aroma to the Queen, and infinitely superior in every other respect, being without dispute the noblest Pines in cultivation. The Queens weigh, on an average, at Versailles about 3lbs., in the open ground; some few have reached 4lbs., or more; but very many have also been less than 2lbs.; those in pots have been somewhat smaller—the difference in size of this kind under the two systems has not varied more than one-fifth; while the Cayenne and Providence have increased more than one-fourth. The number cultivated in this garden is above 2,000; more than two-thirds are Queens; then follow Providence, Cayenne, Enville, and Jamaica. Many others are grown for the sake of variety, such as Antigua, Poli blanc, Moscow, Queen, &c. &c.; but the first-named sorts constitute the grand resources for the Royal family and Court. In a few days I will send another paper on this subject, and also a description of some seedling Pines, which have been lately obtained in Paris and Versailles, as well as of the different boilers now in use.

Societies.

BOTANICAL SOCIETY OF EDINBURGH.

THIS Society held its second meeting for the season on Thursday, the 14th ult.—W. C. Trevelyan, Esq., in the chair. Mr. C. Lennox, Junior, Edinburgh, was elected a Resident Member. A collection of specimens, from Upper Lapland, presented by A. Garrick, Esq., was placed on the table. Professor Graham read the continuation of his botanical tour in the north of Scotland and Jersey, in the course of which he mentioned the various plants observed, as far as peculiar to those districts, or only of rare occurrence in Scotland. He was rather surprised to observe species growing in considerable quantity that have, for the most part, been very sparingly supplied to the Society's —a circumstance which shows the carelessness of Scottish Botanists keeping in view, when making their annual collections, that such species, though not uncommon in them, must be always in demand among their Scotch brethren. The Professor also made some observations on the climate and general aspect of the island of Jersey, in reference to its height above the level of the sea, the nature of its soil, &c., as bearing on the vegetation. At the close of public business the meeting proceeded to the election of office-bearers for the present year, when the following gentlemen were appointed:—viz., President, Professor Graham; Vice-Presidents, Dr. Neill, David Stewart, Esq., W. C. Trevelyan, Esq., and W. H. Lowe, Esq., M.D.—*Edinburgh Evening Post.*

ENTOMOLOGICAL SOCIETY.

Jan. 1.—G. Newport, Esq., in the chair. A new part of the Transactions of this Society was announced, and laid upon the table. A list of officers for the ensuing year was read over. Mr. Ingpen exhibited a birds' nest, apparently belonging to the hedge-sparrow, which had been built during the past month. An extract was read of a letter from Mr. Fortnum, of Adelaide, in South Australia, to the Rev. F. W. Hope. He had obtained a Phasma, with one of its legs broken off, and he had fed it on the leaves of the Gum-tree, and on shedding its skin, in the place of the leg which was broken off a new one, but very small and imperfect, had made its appearance. At the second time of shedding the skin the leg was much larger, till at last, after four sheddings, it assumed a natural size. A remarkable fact in the habits of Phasmides is, that the moment they are out of their old skin they commence eating it. Mr. Fortnum had captured at Adelaide three species of Mantispa, and also of Ascalaphus. He had found no Necrophagi. A communication was read from Dr. Thomas Savage, in which he stated that he had discovered in tropical Africa a new species of Mecycenorhina, very closely allied to M. polyphemus. An extract of a letter from Colonel Hearsey to Mr. Westwood, from central India, was read. He had taken abundance of Diopsæ, the double-headed fly, at different times and in different places. Mr. Westwood described two new species of snored Beetle, for which he proposed the name Ketocerus. They are most nearly allied to the genus Heloc-eanthada. The President referred to Mr. Fortnum's remarks on the reproduction of the legs of Phasmæ. He had found that the Myriapods possessed the same power of reproduction, and he had seen the legs and antennæ of the Julus and Lithobius both reproduced. This reproduction did not take place when the animals had ceased to grow. He did not consider Swammerdam's theory of the developement of one skin or skeleton within another at all borne out by the facts of the case. Mr. Waterhouse thought that the constant reproduction of the parts in Crustaceous animals was accounted for by the fact that they never came to maturity. There was not a period, as in insects, when they ceased to enlarge and throw off their skins. Other remarks were made by Messrs. Yarrell, Marshall, Westwood, and others.

Reviews.

Lessons on Animals, Vegetables, and Minerals. By Mrs. Marcet. 12mo. Longmans.

THIS is a trifle, produced with the skill which its authoress is well known to possess; but only suited to the very youngest of children. It is, in fact, in some measure, an anticipation of the knowledge which the ordinary events of a child's life are sure to produce, unless very extraordinary means of obstructing knowledge are resorted to.

That the admirable arrangements of the creation are far beyond the comprehension of man, is only denied by those who are ignorant of the extent of their own ignorance. Nevertheless, we are no great admirers of the forced construction placed by some people upon very common facts. We should have thought that so clever a person as Mrs. Marcet would be above all *ad captandum* speculations; and yet we are reluctantly obliged to inquire what else is the following:—

"There is an umbrella over the stem of every tree to prevent the rain from wetting it.

"The children laughed and wondered what the teacher meant. He then showed them the print of an Oak, saying, look at the head of this tree; is it not very much like the shape of an umbrella? and it answers the purpose of one completely, for it prevents the trunk of the tree from being wetted. You see how good God was when he made the trees, to give them such a shape that the rain cannot reach the stems to rot them."

Surely we need not add that this is entirely wrong; and that the office of the head of a tree is anything rather than to prevent water falling on the trunk and rotting it. If it were really as Mrs. Marcet states, what would become of all the unfortunate trees grained by the hand of man, handles, with which carpenters and other tradesmen

NOTICES OF NEW PLANTS WHICH ARE …USEFUL OR ORNAMENTAL.

CATTLEYA …

It may be grown in a pot, if desired; but this system is … conformably in accordance with its habits.—*Paxton's Magazine of Botany.*

Tropæolum speciosum. Spiny Tripitilon. (*Herbaceous Perennial.*) Compositæ. Synganesia. Æqualis.—There is a striking … about the vivid blue tint of the blossoms of Tripitilon … which most always render it an object on which it is … to gaze; until the extreme neatness of these flowers, … their copious production in dense heads, is another charac… which adds to its effect. Writing of it in the "Botanical …," Dr. Lindley remarks that "it is a native of Chile, … it appears to be exceedingly common, and is called Semper… on account of the permanence of its deep azure flowers. It … long been known to botanists conversant with the Chilian … as a most desirable species to introduce, and repeated … have been made to acquire it, but in vain, until seeds … into the hands of Mr. Frost, gardener to the Countess of … ville, at Brympton." Mr. Frost has been very successful in … it; but the specimens exhibited by him at the Chiswick … have not been free from that brownness in the lower … and that partially unhealthy aspect, which are too com… to the species. It flowered well last autumn with Mr. Glen… of the Farnham-green Nursery. He writes us respecting … as follows:—"Its scarcity in collections is attributable to … causes; viz., the sparing way in which it has hitherto been … and the want of the true desideratum of culture, and the … difficulty attending its preservation during winter. I per… it by division of the roots. This means of increasing it, … is a very sparing one. It should be divided early in … autumn, that the plants may be established before the damp … It must not from this be inferred that the plant is … tender. On the contrary, it will resist considerable intensity of … without injury. It will produce seeds, although not freely. … plant here has afforded me a little seed; and I have now plants … obtained by both modes of increase. The seeds should be sown … immediately when gathered, in light sandy soil, and placed in a … house. When sufficiently advanced, the plants should be … potted singly in small sixties, and kept in a dry part of the green… house during winter." The great point in growing the plant is … evidently to preserve it from superfluous dampness. To aid in … effecting this, the heath-mould in which it is potted should be … particularly fibrous and open, and have a little turfy loam and … leaf-mould mixed with it, besides a small quantity of broken … sandstone. The three divisions of the pappus of the flower have … originated the generic name, which is from *treis*, three, and … *pilion*, a feather.—*Paxton's Magazine of Botany.*

Achimenes pedunculata. Long peduncled-flowered Achimenes. (*Stove Perennial.*) Gesneraceæ. Didynamia Angiospermia. The soft and exquisite light purple of the blossoms of *A. longiflora*, and the glowing crimsony scarlet of *A. coccinea*, have been a worthy companion in the deep vermilion and orange of *A. pedunculata*, which is likewise a species so peculiar in habit, that it presents a fine change from the others. It was found by Mr. Hartweg, the collector for the Horticultural Society, in the shady woods of Santa Maria, Guatemala, and sent to the Society's garden at the same time as *A. longiflora* and *A. coccinea*. One of its chief recommendations is, that it continues to flower late in the season, specimens were blooming freely in the nursery of Mr. Mountjoy, Ealing, in October last. Being of a strong erect habitude, it grows to the height of eighteen inches or two feet, and bears its handsome blossoms towards the top of the stem, on long axillary peduncles, which have usually two flowers on each. Their colour is a dark vermillion, with a light orange-coloured throat, and dark stripes in it extending nearly across the segments of the limb. Curious little bulb-like tubers are formed on the upper part of the peduncles, along with minute leaves. To have this Achimenes in high perfection, it should be grown rapidly when it begins to start. A warm moist atmosphere will best accomplish that object; and if these conditions be supplied through the medium of bottom-heat, they will be all the more congenial. A moderately rich loamy soil is requisite. Throughout the winter the plant will remain in a state of rest; but it does not lose its stems so early as some of its allies, and consequently requires to be watered with caution in the autumn. We presume that, like the rest of the species, it produces tubers in abundance from its roots, and that by these it may be readily propagated. From the rich colours of its flowers, it offers a good companion to the hybridist for blending with such species as *A. grandiflora* or *rosea*. Indeed, with the former, its pale blossoms would be improved in size; while *A. rosea* would be altogether ameliorated by the intermixture of its hues.—*Paxton's Magazine of Botany.*

Clematis montana. Var. *grandiflora*. Mountain Virgin's Bower. Large-flowered variety. (*Hardy Climber.*) Ranunculaceæ. Polyandria Polygynia.—This handsome variety of the very elegant Chinese mountain flowered in the open ground, in the garden of Mr. Veitch, of Exeter, at the same time with the ordinary form of the plant, of which the blossoms are not half so large. Both are well worth cultivating in gardens where there is a recommendation for climbers. The profusion of large flowers, the delicacy of their colour, and their fragrance, are strong … This species is a native of Northern India; … Hardwicke, Gamble, collected it at Chitkool, in the Valley of … Simla, Himalaya, in April. Mr. Blinkworth gathered it in … Nepaul, where it appears to be prevalent in the Himalayan … mountains, from elevations of from 5,000 to 7,000 feet above the … of the sea. In this country it flowers in early summer, and … ripens seeds in the month of September. In a few years it ought … to become a very general plant, for it strikes readily from cut… and layers.—*Curtis's Botanical Magazine.*

THE NATURALIST'S CORNER.

Tea, Chocolate.—Cocoa-beans, from which chocolate is … prepared in lumps or cakes, or in … to sell in the shops under the name of cocoa, are … from the Theobroma Cacao of botanists. The fruit resembles … in commonly about three inches in … In growth on the outside, and has a yel… The … are … in a pulpy substance, which … to the … The … are … and … and … Four trees … cultivated … money in some parts of America. Chocolate … seems to have been first manufactured in Mexico, and the … Castile ladies *were* for a long time so fond of the beverage, … that it was habitually served to them even in church by … slaves.

74. Malloiæ.—Among the very numerous species of *Malvaceæ*, several are of essential service to man. As … emollients they are well known in medical practice; the Marsh-mallow (*Althæa officinalis*) being one of the most useful among this kind of remedial substances, and a large proportion of the whole order being capable of supplying its place. The hairy covering of the seeds of the various species of *Gossypium* forms the raw cotton, so important to our manufacturers. *Malva tricuspidata* is used by the negroes in the West Indies as a substitute for soap. The seeds of *Hibiscus abelmoschus* are warm and musky, and are employed in perfumery as a substitute for musk; those of *Hibiscus esculentus* form the ochra, so much used in hot countries as a mucilaginous ingredient in soups. A few species are acid, especially *Hibiscus sabdariffa*. Finally, the tenacious fibres procured from the inner bark of many kinds of malvaceous plants, form a good description of cordage. *Hibiscus elatus* and *tiliaceus*, and several kinds of *Sida*, are principally used for this purpose.

Miscellaneous.

Mr. Loudon.—Mr. Loudon's father was a farmer, residing in the neighbourhood of Edinburgh, where he was very highly respected; but Mr. Loudon was born on April 8th, 1783, at Cambuslang, in Lanarkshire, where his mother's only sister resided, herself the mother of the Rev. Dr. Claudius Buchanan, afterwards celebrated for his philanthropic labours in India. Dr. Buchanan was several years older than Mr. Loudon, but there was a singular coincidence in many points of their history. The two sisters were, in both cases, left widows at an early age, with large families, which were brought up by the exertions of the eldest sons; and both mothers had the happiness of seeing their eldest sons become celebrated. Mr. Loudon was brought up as a landscape-gardener, and began to practise in 1808, when he came to England with numerous letters of introduction to some of the first landed proprietors in the kingdom. He afterwards took a large farm in Oxfordshire, where he resided in 1809. In the years 1813-14-15, he made the tour of Northern Europe, traversing Sweden, Russia, Poland, and Austria; in 1819 he travelled through Italy, and in 1828 through France and Germany. Mr. Loudon's career as an author began in 1803, when he was only 20 years old, and it continued with very little interruption during the space of forty years, being only concluded by his death. The first works he published were the following:—"Observations on laying out Public Squares," in 1803, and on "Plantations," in 1804; a "Treatise on Hothouses," in 1805, and on "Country Residences," in 1806, both 4to.; "Hints on the Formation of Gardens," in 1812; and three works on "Hothouses," in 1817 and 1816. In 1822 appeared the first edition of the "Encyclopædia of Gardening;" a work remarkable for the immense mass of useful matter which it contained, and for the then unusual circumstance of a great quantity of woodcuts being mingled with the text: this book obtained an extraordinary sale, and fully established his fame as an author. Soon after was published an anonymous work, written either partly or entirely by Mr. Loudon, called the "Greenhouse Companion;" and shortly afterwards "Observations on laying out Farms," in folio, with his name. In 1824, a second edition of the "Encyclopædia of Gardening" was published, with very great alterations and improvements; and the following year appeared the first edition of the "Encyclopædia of Agriculture." In 1826 the "Gardeners' Magazine was commenced, being the first periodical ever devoted exclusively to Horticultural subjects. The "Magazine of Natural History," also the first of its kind, was begun in 1828. Mr. Loudon was now occupied in the preparation of the "Encyclopædia of Plants, which was published early in 1829, and was speedily followed by the "Hortus Britannicus." In 1830, a second and nearly re-written edition of the "Encyclopædia of Agriculture was published, and this was followed by an entirely re-written edition of the "Encyclopædia of Gardening," in 1831; and the "Encyclopædia of Cottage, Farm, and Villa Architecture," the first he published on his own account, in 1832. This last work was one of the most successful, because it was one of the most useful, he ever wrote, and it is likely long to continue a standard book on the subjects of which it treats. Mr. Loudon now began to prepare his great and ruinous work, the "Arboretum Britannicum," the anxieties attendant on which were, undoubtedly, the primary cause of that decay of constitution which terminated in his death. This work was not, however, completed till 1838, and in the meantime he began the "Architectural Magazine," the first periodical devoted exclusively to architecture. The labour he underwent at this time was almost incredible. He had four periodicals—viz., the "Gardeners'," "Natural History," and "Architectural Magazines," and the "Arboretum Britannicum," which was published in monthly numbers, going on at the same time; and, to produce these at the proper times, he literally worked night and day. Immediately on the completion of the "Arboretum Britannicum," he began the "Suburban Gardener," which was also published in … with the "Hortus Lig… and in 1838 appeared his edition of Repton's "Landscape Gardening." In 1840, he re… the editorship of the "Gardeners' Gazette," which … the … year, and … the "Encyclopædia of Trees and Shrubs." In the same year he completed his "Suburban Horticulturist;" and finally, in 1843, he published his work on "Cottage, Farm, and Villa Architecture," the last separate work he ever wrote. In this list the minor productions of Mr. Loudon's pen have not been omitted; but it may be mentioned, that he contributed to the "Encyclopædia Britannica," and to the "Dictionary of Science;" and that he published numerous supplements, from time to time, to his various works. No man, perhaps, has ever written so much, under such adverse circumstances, as Mr. Loudon. Many years ago, when he came first to England (in 1803), he had a severe attack of inflammatory rheumatism, which disabled him for two years, and ended in an anchylosed knee, and contracted left arm. In the year 1820, whilst writing the "Encyclopædia of Gardening," he had another severe attack of rheumatism; and, the following year, being recommended to go to Brighton to get shampooed at Brighthomat's baths, his right arm was there broken near the shoulder, and it never properly united. Notwithstanding this, he continued to write with his right hand till 1826, when the arm was broken a second time, and he was then obliged to have it amputated; but not before a great breaking up of the frame had commenced, and the thumb and two fingers of the left hand had been rendered useless. He afterwards suffered frequently from ill health, and his constitution was finally undermined by the anxiety attending on that most costly and laborious of all his works, the "Arboretum Britannicum," which has, unfortunately, not yet paid itself. He died at last of disease of the heart, after suffering severely about three months; and he retained all the clearness and energy of his mind to the last. His labours as a landscape-gardener are too numerous to be detailed here, but that which he always considered as the most important, was the laying out of the Arboretum so nobly presented by Joseph Strutt, Esq., to the town of Derby. Never, perhaps, did any man possess more energy and determination than Mr. Loudon; whatever he began he pursued with enthusiasm, and carried out, notwithstanding obstacles that would have discouraged any ordinary person. He was a warm friend, a most kind and affectionate in all his relations of son, husband, father, and brother; and he never hesitated to sacrifice pecuniary considerations to what he considered his duty. That he was always most anxious to promote the welfare of gardeners, the volumes of this Magazine are ample witness; and he laboured not only to improve their professional knowledge, and to increase their domestic comforts, but to raise their moral and intellectual character.—*From the Gardeners' Magazine*—which, we regret to say, has been finally discontinued, after a useful existence of 18 years.

Casalpinia coriacea.—The seeds of a plant … exhibited on the 7th of Dec. at the Royal Society of Horticulture, Paris, under the name of Casalpinia coriacea. … it was an error, for they were the seeds of Cæsalpinia … which are used in America for tanning. I saw the tree … in the hothouses at Neuilly and elsewhere, where the … seeds of this tree grow in the tan-bed. It is a remarkable fact, that the tannic acid produced by tan-bed … this tree to grow, whilst in its fresh state it destroys the … embryo of many vegetables. The tanning principle is … in the sides of the pods and not in the seeds.—*Paxton.*

CALENDAR OF OPERATIONS

For the ensuing Week.

The Gardening Directions in this Paper have … hitherto entrusted annually to some one Gardener … known skill and reputation; and we hope our readers will agree with us in thinking that the manner in which Mr. Paxton, in the first instance, and subsequently Messrs. Whiting and Beaton, fulfilled their task, was worthy of all praise. It has, however, been found that a weekly duty of this nature presses too heavily upon any one diligently engaged in the business of a Gardener; and moreover, no one person, however great his talent, can be supposed to understand all branches of cultivation equally well. We have, therefore, decided upon altering our plan so far as to confide the important duty of conveying … instruction or advice to gardeners all over the United Kingdom, to some of the most intelligent persons of our acquaintance; and by this means we trust to render the Calendar all that it is possible that it should be. We may be expected to state who the authorities are, which we have been so fortunate as to secure. We must, however, decline affording the curious any information on that point, for the following reason. The labour of writing the Calendar is in itself very considerable, when, in addition, the writer is exposed to answer questions, upon all kinds of subjects from various correspondents, the trouble is increased beyond endurance, and, in fact, we do not feel justified in asking any one to be exposed to it. This we conceive sufficiently explains our motive for concealing the names of our Calendar friends.

I.—HOTHOUSES, CONSERVATORIES, &c.

The temperature of the stove should not exceed 80° with fire-heat, and a fall of 10° may be allowed at night in … cold weather. Although all plants now at rest should be kept comparatively dry, they will require to be looked over … to see that they do not suffer for want of water, particularly those nearest the pipes and flues. Orchideæ may be potted up-to-date, or fixed to wire baskets at any time when … can be done in the open air, but they need not be watered … enticed to grow for making them.

Conservatories.—Old-established plant-houses this season will require a … quantity of fire-heat. I have seen Conservatories with … plants that grew very well that did not receive air by the … for months together. In order to keep down damp … in … plants, when … the paths should not be swept when … admitted. Chrysanthemums are often … in … to show the leaves. Very little … will be … now, and that should be … or ten degrees …

(temperature of the house, which has to about 45°. ... The temperature of this house should not be ... above 50° now; the watering ought to be finished ... the day, and the plants should be constantly looked over ... them free from dead leaves, insects, or moldered mould ...

Pits.—A multitude of half-hardy plants may be kept in ... without any manner of artificial heating; but at the ... notwithstanding all care, some of them may be lost; ... however, will occur in the best plant-houses.

Forced Flowers.—As I promised I shall have a good deal to ... under this head. I shall only now remark that where ... forcing are in great request two divisions are necessary ... such kindly plants as do not succeed in a high temper- ... with means for bottom-heat, for Gardenias and ... Almost all plants, however, in forcing, are ... bottom-heat.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

... the late frost and snow, but little can be done here at ... except where alterations are going on, and then the ... of ground for planting may be proceeded with; but it ... desirable to keep the frozen or snow-saturated surface ... of the top, as, if thrown into the bottom of the trenches, it ... remain cold for a long time. Keep the walks and Grass as ... and clean as possible, to compensate a little for the want of ... at this dull season.

Flower Garden.—Beds containing autumn-sown Annuals ... be the better for a few branches of evergreens stuck into ... to shade the plants from bright sunshine after frost, and ... protect them from drying winds. Plants generally in the open ... are tender this season, and must be watched accordingly.

Pits and Frames.—The young stock of plants in these struc- ... are in a growing state, and therefore will require to be ... carefully guarded against frost; but give them all the air and ... possible on fine days, and keep them free from decayed ... and moisture. Where Hydrangeas are required to turn ... the beds in the flower-garden in April and May, they must ... to be put into the forcing-house. Get dung prepared, to form ... propagating bed next month.—*W. P. A.*

III.—FLORISTS' FLOWERS.

As this matter does not press, we defer this part of our Calendar ... the present.

IV.—PINERIES, VINERIES, &c.

Pineries.—In undertaking to write this department of the ... I feel that I can advance little that will be of service to ... who possess the former Numbers of the *Chronicle*, or to ... practical gardeners; but if what I may say from time to ... will be of use to the less experienced, it will afford me ... pleasure. Perhaps there never was a time when more ... was felt in the cultivation of the Pine-apple, than at ..., or when the spirit of competition ran higher among ... generally, than it is likely to do during the coming ... If the fruiting-pit is kept at 60° by night it will be ..., raising it 5° or 10° by day, according to the clearness ... *atmosphere*. Take every favourable opportunity of admit- ..., water sparingly with a fine rose pot; it is scarcely safe ... unless rose at this season. Keep a moist atmosphere, ... remember that steam is never of so great a density as to ... the leaves, and run into the hearts of the plants, or into ... the pot. Maintain a steady heat of 80° in the tan, or ... the Pines are planted out. The young stock should not ... more heat than is sufficient to keep them from going to ... 60° by night is quite high enough during this month. Dress Celery from ... which may yet for a considerable time if taken up with ... roots, in rows 18 inches apart, and clean dry earth put ... the rows, so as the hearts do not touch moist earth. ... and defend all stored roots and fruits.

Fruit-trees.—Mild weather for pruning, nailing, and ... It is always advisable to get on forward as possible with ... Standard trees in gardens. Protect young newly-planted ... from frost. The wood of fruit-trees will not be injured ... by frost when in a dormant state, but when in a growing ... the case is different. Protect from frost also Peaches ... and Apricots, and Apricots against which have been unable ... some time ago. The free exposure of these to all rides would ... render them better hardened, and from not being contiguous to ... the wall, they would not be so easily excited, nor in so much ... danger of having their sap-vessels burst by severe frosts. In addition to this, the stems might be bound round, not over ... closely, with hard twisted straw bands, and a little long litter ... thrown over the border to the width of four or five feet. This is a fine opportunity for moving soil, turning composts, and wheeling manure. Do not forget to give a little of the latter as a ... mulching or top-dressing to your Strawberry-beds, if you want to have very superior fruit next season.—*R. J.*

VI.—ARBORICULTURE.

Old Woods.—The felling of timber-trees not designed for peeling the bark should be forwarded at all convenient times. Filling up vacant spaces, when the weather permits, with young plants suitable to the soil, locality, and demand, should be proceeded with.

Coppice.—Put forward the cutting of the undergrowth for cor- ... rods, sheep-hurdles, watling, hop-poles, hoops for barrels, and ... any other purposes required; but if a vigorous aftergrowth is wished, I would prefer leaving such work till February, March, or April, for reasons I may give at a future time. Clear out open drains, and make fresh ones where wanted: this work might be done in frosty weather. Fill up open spaces with young plants suitable to the soil—this should always be attended to.

Young Plantations.—Make new ones. Trench the ground, where a speedy growth is desired for immediate effect, for blinds or shelter, especially when large plants are used. In plantations advanced in growth, begin to thin out some of the supernumerary and inferior kinds when they begin to crowd each other, or, rather, shorten the side-branches of those intended to be taken out, for a few years beforehand.

Hedge-row Trees.—Now is the time to plant properly-prepared plants of select kinds; and as winter and spring is the season for pleaching and regulating hedges, great care should be taken to preserve what young trees there may be of the proper kinds that often naturally spring up in them, and to plant fresh ones where required. Care should be taken not to divest them of all their lateral side-branches—only the largest; and always preserve one upright leader.

Nursery Work.—I intend to confine my remarks chiefly to Nurseries of private individuals.—Make Nurseries where required. Trench the ground for planting out in rows seedling forest-trees, (either raised privately or purchased from public Nurseries,) and for sowing seeds, nuts, or berries of the commonest kinds of plants—such as Hollies, Haws, Acorns, Spanish Chesnuts, Walnuts, and any others desired. Protect young plants from the depredations of hares and rabbits, if you can;—in some future Number I will say how, on a limited scale.—*W. B.*

VII.—COTTAGERS' GARDENS.

The unusual mildness of the season until within the last few days will have enabled the Cottager to be pretty well forward with his operations in the garden, and he will now have little to do in the way of digging, &c. for some time. As we may, however, yet expect to have some severe weather, any plants, such as China Roses, that are rather tender, should be protected, for having been somewhat excited by the late fine weather, frost will have more effect upon them, and might prove very injurious. Any hardy creeper on the cottage, as a Clematis, if not previously done, may now be neatly trained. Plants in pots, such as Pelargoniums or Fuchsias, should have an abundance of air given them every fine day; they should be watered sparingly, and this should always be done at this season in the morning.

Vegetables.—Marshall's dwarf Prolific and Mazagan Beans are the kinds generally used for early crops; the latter is the hardiest, and if not done before this, some may be sown for an early crop as soon as the weather will allow, in shallow drills about 18 inches apart, on a warm border. They may be planted in the row about three inches apart, and covered about two inches deep. On the first fine day a sowing of the Early Frame or Charlton Peas may be made, on a warm sheltered border, which should have been ridged crosswise; draw the drills within three inches of the bottom on the south side of the ridge; this will keep the seeds dry, and prevent them from rotting, as sometimes happens, especially in a retentive or clayey soil. For this crop the seeds should be sown pretty thick, and in case of intense frost they should be protected by Fern or Furze; some of the latter chopped may be put in the drills to prevent the ravages of mice.

Fruit.—Any fruit-trees trained against a wall may now be pruned, have their shoots nailed quite straight, and disposed so as to cover the wall equally. Standards may also now be pruned, taking care to cut out all cross branches. Gooseberries and Currants, if not previously pruned, may now be done, so as to allow the ground to be dug amongst them.

Flowers.—Bulbs, if any, such as Daffodils, Anemones, or Tulips, if not already planted, the earliest opportunity should be embraced for getting them in. Those planted in October will now be above ground; they should be covered with Fern to keep them from frost. Every unsightly object should be removed from the flower-borders, so as to give them a neat appearance.—*Mc. H.*

State of the Weather near London for the week ending Jan. 4, 1844, as observed at the Horticultural Garden, Chiswick.

Shortly will be published,

BRIEF REMARKS on some subjects connected with the CHOICE of WHEAT for SEED; interesting to Farmers, Corn Factors, and Bakers.

By Sir G. S. MACKENZIE, Bart., F.R.SS.L.&E., &c.

Simpkin and Marshall, London; M'Lachlan & Stewart, Edinburgh.

PRACTICAL DIRECTIONS FOR THE CULTIVATION AND GENERAL MANAGEMENT OF COTTAGE ALLOTMENTS, with Plans for laying them out for five years. Also, Hints on Keeping Pigs, on Service, &c.; with a Form of Rules and Agreements By CHARLES LAWRENCE, Esq., of Cirencester. A Third Edition is being printed by Messrs. MANNING and Co., of Ivy-lane, Newgate-street; by whom all orders will be supplied, which may be sent to them before the 12th of January, at 20s. per hundred copies.

The Agricultural Gazette.

SATURDAY, JANUARY 6, 1844.

It is probable that most of our readers have seen the prospectus which has for the last few weeks been published in this and other Papers advertising the addition of an *Agricultural Gazette* to the *Gardeners' Chronicle*. There is, however, a good deal connected with the fact thus advertised that perhaps may not have occurred to some of them, and we propose at present to enlarge upon one of the subjects thus suggested.

The whole business of farming naturally consists of two branches, the one of which refers to the *production* of Vegetables, Wheat, and other Grains, Turnips and other roots, Clovers, Grasses, &c; and the other of which refers to the *conversion* of some of these into animal substances—beef, mutton, bacon, milk, wool, &c. So far from this being merely an ideal division, it is one which, in some parts of the country, actually exists; so that, in such districts, there are two distinct lines of business connected with the land—that of the farmer, who either sells his green crops on the ground, or carries them to his buildings to dispose of them there; and that of the dealer, who purchases these crops and brings his sheep and his cattle on the farm to consume them. The principles upon which these two lines of business depend for their successful prosecution, are, of course, entirely distinct, and so also, when they are separate, are the qualifications required by those who would engage in them.

Now, it is with reference to the first only of these two branches of the business of the farmer that Agriculture can be said to come in contact with Horticulture—it is in the first part of the business only that the principles upon which successful farming depends are the same as those which should regulate the practice of the gardener; and the fact of a Farmers' Paper being established by the conductors of the *Gardeners' Chronicle*—an Agricultural being thus grafted by them upon a Horticultural periodical—may be considered as an intimation of their wish to direct the attention of their readers more particularly to the details of the first branch of farming and to the principles upon which those details depend.

The attention of the Agricultural world has, indeed, been for many years past, so much—and were it not for the writings of the last year or two, we might say so exclusively—directed to questions connected with the breeding and management of live stock, that to bring forward a new periodical in addition to those which still continue to draw attention to this branch of farming would be a superfluous and perhaps an unsuccessful attempt. Our readers must not, however, understand this expression of our opinion to imply that we shall altogether neglect the important branch of farming to which we allude. The conversion of his green crops in the most profitable manner can hardly interests every good farmer to admit of this. A great deal of light, too, has been lately thrown upon this subject by Professor Liebig's exposition of its dependence upon the laws of organic chemistry and animal physiology, and to the practical application of these laws we shall frequently invite the attention of farmers. All that we wish to express is our decided opinion, that, considering the art of *cultivation* as the most important branch of farming, great good would result, could we succeed from the neglect with which comparatively speaking, it has been hitherto treated over large districts in this country.

In connection with this, we wish to impress upon our readers what we are very sure of—that more good will result from an endeavour to concentrate, and apply the knowledge already possessed, and to diffuse more extensively with that amount of practice adopted in this country, under the various circumstances of soil, climate, and markets by which Great Britain is distinguished, than by any attempt to extend our knowledge of abstract truth. Theories of Agriculture, [illegible] we [illegible] to name Liebig, [illegible] Johnston, [illegible] Sir H. Davy, and other [illegible] are [illegible] to-day, consisting as it does of many of the most experienced and successful Farmers in every part of the kingdom, who have given us assurances of their approval and co-operation. And, with them, we invite our agricultural readers to use our columns as the channel for the interchange of opinions on the numerous subjects connected with our common occupation, and through which to publish, for the benefit of all, the results of their agricultural experience.

It is said that the advantage of a Farmers' Club to its members consists in the opportunities which it offers to each, of acquainting himself with the agricultural knowledge and practices of all the others The point of perfection in the course of usefulness on which we shall endeavour to enter will have been then only attained when all our readers shall have been thoroughly brought to consider themselves as the members of one large and active Farmers' Club, ourselves occupying the place of the organs of speech and hearing, through which they may communicate with one another.

To these general observations we have only to add, that the following are the heads under which the matter of the *Agricultural Gazette* will be arranged:—

1. LEADING ARTICLES, which will generally refer to subjects suggested by the time of the year, and the farming operations of the season.

2. ORIGINAL MATTER, in the form of special papers on Agricultural subjects, such as the cultivation of our most important plants, the management adopted in certain branches of farming—the dairy, for instance, the weeds of Agriculture, Agricultural Mechanics, the Agricultural history and present condition of certain districts, and the various sciences, such as Chemistry, Animal and Vegetable Physiology, Geology, &c., on which the success of the farmer's practice depends. Here, too, any translations which it may be deemed advisable to make from foreign works on Agriculture will be placed; and we this day give No. 1 of a series of papers from the chapter on Mineral Manures, in Sprengel's important Work on that subject.

3. HOME CORRESPONDENCE.—This will, we hope, become the most valuable section of the contents of our Paper. The conditions under which farming is carried on in this country are so various, that it is impossible for any *one* system of Agriculture to be of universal application. An Agricultural periodical, to be *generally* useful, must therefore contain information derived from sources widely spread over all parts of the kingdom. We have already received promises of contribution to this section of our Paper from many different quarters; and we doubt not that our readers, seeing its usefulness, will assist in the compilation of this common stock of Agricultural information. We shall, in our next Number, explain more fully our views upon this subject.

4. PROCEEDINGS of the English, Highland, and Irish Agricultural Societies; and of the various County Agricultural Societies, and Farmers' Clubs. We may, however, as well announce at once that we do not propose to report after-dinner speeches, except upon very special occasions.

5. REVIEWS OF AGRICULTURAL WORKS.

6. MISCELLANEOUS notices of events of general Agricultural interest, extracts from works on Farming subjects, &c.

7. NOTICES TO CORRESPONDENTS; a department of the Paper which we shall endeavour to make of real use. We engage that Agricultural queries sent to us shall receive the attention of those competent to answer them.

8. REPORTS OF THE MARKETS.—Under this head, will be given as full a statement as the farmer will in general require for his own guidance; and it will be obtained from unexceptionable authorities, whose names will, we trust, be eventually attached to the several sections of which it will consist. Mark-lane and Smithfield, the Wool-markets of Yorkshire, the Hay, Potato, Butter and Cheese, Hop, and Manure markets, will be fully reported.

So much for the proposed contents of the *Agricultural Gazette*. As to the principles which will guide us in the selection of matter, it will be sufficient to say that ALL PARTY questions are to be excluded, as well as everything at variance with that courtesy which we all owe to each other. In the execution of our task we have no small satisfaction in being able to rely upon the support of some of the most distinguished members of the leading Agricultural Societies, of some of the most eminent scientific men who are now turning their attention to Agriculture, and of many of the best practical farmers, Agricultural engineers, and Agricultural writers of the present day.

In the early part of last year, the Editor of the *Gardeners' Chronicle* alluded to a suggestion which had been thrown out on the importance of experimental co-operation among Agriculturists in the following terms:—"When a philosopher works carefully in his cabinet, acquainted accurately with the nature of all the agents spread before him, and alive to all the disturbing influences that may affect his results, he knows that one experiment is as good as a hundred, and a necessity for repeating it may not be felt; for when natural causes are exactly alike, the same effects must as surely follow them as when figures are dexterously combined by the arithmetician. But the cultivator of the soil is in a wholly different position: he has to deal with materials which, although they are called by the same name, may be really very different in their nature. He knows very little about them; a thousand circumstances unobserved by his untrained eye may exist to disturb his results, and the consequence is, that all his experiments must be varied and repeated till *a series of averages* will form a rough but sufficient check to his conclusions. We may fairly doubt whether the course operations of Gardening and Agriculture will ever bear to be examined in any other way; and if they would bear it, the new results of new practices will certainly fail of carrying conviction to the minds of the mass of the people, unless supported by evidence accumulated upon evidence."

Since the publication of my Letters to the Farmers of Suffolk, I have had an opportunity of conversing with several scientific men on the subject, and they have agreed with me in considering that such a scheme as that which has been suggested, if fairly carried out, would speedily lead to most important results. I have seen, by the local papers, that Mr. Nesbitt has been very effectively inviting some of the Farmers' clubs in Kent to assist in carrying out such a scheme, and he has informed me that several members of those clubs have expressed their readiness to join in any attempt which may be made. I have received a similar assurance from the neighbourhood of Saffron Walden. The Rev. E. Sidney has most intelligently and efficiently been lecturing to the farmers and others, for some time past, in the neighbourhood of Norwich, on scientific subjects bearing upon agriculture; and, from what he tells me, I can feel no doubt that many practical men in that quarter have become capable of fully appreciating, and would be willing to assist in carrying out, a general system of experimental co-operation on the very simple and limited scale proposed. No doubt there are many localities in every county where a similar disposition would be found to prevail. The real difficulty appears to lie in the properly organising some system for the purpose—a difficulty which, the more I think of it, the more I am satisfied is very trifling. I hope, as I may, to find time to occupy these pages with a few remarks upon the subject, suggesting some of those correspondents who may be disposed to discuss it with me, either to state objections or throw out suggestions, as they may see cause in doing so; in short, freely to examine a question which some persons among the best qualified for judging of its merits consider to be one of real importance to the interest of Agriculture. I have promised on this occasion to state the results of an experiment with which I have been favoured by C. Bree, Esq., of Stowmarket; and I hope, it may tend to remove the scepticism of certain persons who as yet have acquired no faith in the advantages to be derived from science, and that it will assist in convincing them how possible it is for a chemical proficient, like Liebig, to make suggestions which are likely to lead to important practical results. Liebig had asserted that certain substances, as sulphuric acid, gypsum, &c., might be serviceably employed in fixing the ammonia which escapes during the putrefaction of animal and vegetable manures. Mr. Bree's experiments were directed to the verification of this assertion, so far as regards liquid manure. He filled, during the months of February and March, 1843, three tubs, A B C, with 50 gallons each of human urine. Into A he poured, at intervals, 20 oz of sulphuric acid; in B he placed 8 lbs of burnt and 15 lbs of unburnt gypsum; the urine in C was allowed to putrify without anything being done to it. In A, decomposition appeared to be completely arrested; in B it was protracted, but ultimately appeared to proceed as though no gypsum had been present.

Six patches of ground were measured out, each containing eight perches, and to these the manure were applied, whilst a seventh patch of 8½ perches was left unmanured for the purpose of obtaining a comparative experiment. These patches were treated in the following manner previously to the seed being sown:—

No. I.	10 gal. of urine	and 20 gal. water	from tub A.
II.	15 "	and 15 " "	(sulp. acid.)
III.	10 "	and 20 " "	from tub B.
IV.	15 "	and 15 " "	(gypsum.)
V.	10 "	and 20 " "	from tub C.
VI.	15 "	and 15 " "	(nothing.)
VII.	No manure applied.		

Each patch was sown on 6th April with 13½ pounds of Barley and Clover. No distinct difference was at first perceivable between the different crops, but the man who sowed the Barley readily pointed out the

best and worst. The Clover was *very strong* where the gypsum was used.

The following were the results obtained:—

No.		Grain.			Straw.
		lbs.	Bush. P.	Qrs	lbs.
I.	10 gals. A. to 20 gals. water	133	2 2	2½	214½
II.	15 ,, A. to 15 ,, ,,	128	2 1	3½	181
III.	20 ,, B. to 10 ,, ,,	109½	2 0	5	146
IV.	15 ,, B. to 15 ,, ,,	108	2 0	2½	159
V.	10 ,, C. to 20 ,, ,,	105	2 0	1	155
VI.	15 ,, C. to 15 ,, ,,	115	2 0	2½	183
VII.	. . . . .	96	1 3	2½	173

From these data Mr. Bree has made the following calculations:—

No.	Per Acre.		Weight per Corn.			
			By Calculation.		By Chondrom.	
	st. lbs.	qr. b. p. qr.	st.	lbs.	st.	lbs.
I.	140 0	13 1 0 2	14	4	15	6
II.	128 12	12 1 1 2	14	13	15	4
III.	126 6	10 3 3 0	14	3	15	8½
IV.	136 4	10 3 0 2	14	5	15	4
V.	130 0	10 1 1 0	14	0	15	4
VI.	164 4	10 3 0 2	15	4	15	4
VII.	137 2	9 2 0 2	14	5	15	4

As I am not acquainted with the Chondrometer, I know not what confidence is to be reposed in this instrument; but Mr. Bree's calculations are somewhat at variance with the results furnished to him (as above) by a practical man who examined his samples by it. It is a little remarkable that No. 3 should beat No. 1, in this description of scrutiny.

So far as they go, these interesting experiments of Mr. Bree afford good evidence for our believing in the importance ascribed to the addition of a little sulphuric acid to liquid manures; but standing alone as they at present do, they afford no data by which we may hope to elicit any very positive information respecting those fundamental *principles* upon which the science of Agriculture must depend. It will need even still closer registration of the actual results obtained, than Mr. Bree has considered to be necessary for the particular object he had in view, before any such applications of these experiments can be made; for in the present instance no account has been kept of the effect produced upon the Clover. If a cow and a horse were fed upon a given quantity of Corn, we must know how much each of them has consumed before we could safely speculate upon the effect which the whole amount had produced upon one of them. Mr. Bree's object, in this instance, has been sufficiently answered by his proving the validity of Liebig's suggestion; and it may be left to parties more directly interested in the improvement of Agriculture to co-operate in a series of experiments, to be devised, for the purpose of ascertaining whatever is really essential to their securing a just economy in practice. It will be necessary to determine to what extent the medicated urine should be diluted, and how often it should be applied, for the purpose of securing the best return at least cost. Time appears to be now an important element which farmers have to secure in these inquiries; for I see that Mr. Brande, in his late lecture to the Royal Agricultural Society, has declared it to be his opinion that the time is now arrived when Chemistry may be made serviceable to Agriculture; and there can be few chemists who are better able to form a judgment on this point than himself. But if the time is arrived, no time should be lost. What a different position will the Agricultural body be placed in at the end of (*x*) years, should the fundamental principles of the theory of Agriculture have become as well established as those of many of the other Industrial Arts—as dycing for instance, and sugar-refining, and brewing, &c.—from that which they must continue to occupy if those principles shall not then have been ascertained!—*J. S. Henslow.*

MANURES.

The labours of those Chemists who have particularly devoted themselves to the Chemistry of Vegetation may be divided into two classes, the theoretical and the practical; the former including inquiries into the higher and more abstruse departments of Organic Chemistry, whilst the latter consists chiefly of investigations into those matters which are most immediately interesting to the farmer; the former seeking to discover the philosophical laws which govern the processes of nature, the latter merely endeavouring to elucidate those laws, as far as may be necessary in order to explain practice, and lead to its improvement. Both these inquiries are of great value, though they have very different objects in view. The philosopher who buries himself in searching out those great laws of the universe, which at once exhibit the wisdom and goodness of the Creator, feels comparatively little interest in the minor details of practical experience; whilst the purely practical man, even if he have the inclination, has not time to follow the more abstruse inquiries of the former; he will naturally ask, what shall I be the better for such knowledge? and how will it benefit me?

Those who would wish to make farmers chemists, propose that which cannot be done, and which, if it could, would do more harm than good. To teach a farmer the theories of chemistry, would be to give him information which it would be totally impossible for him to apply; and on the other hand, to instruct him in what is commonly called practical chemistry would be equally useless, because if he tried to avail himself of such knowledge, he would be more likely to mislead himself, than to profit by his experiments. Farmers are taught how to analyse a soil in a simple and accurate manner, and yet all the information they could derive from such an analysis, would amount to no more than a good ploughman knows after walking across a field; nay, the result of such an analysis would probably be of far less practical value than the ploughman's opinion.

The chemistry which may benefit the farmer is neither philosophical chemistry nor the chemistry of the laboratory, but it is what may be called the chemistry of Nature. Those simple and elementary rules which affect the ordinary operations, either of Nature or art, constantly going on before us. Such knowledge is useful to every one, and, sooner or later, its value will become apparent.

Every farmer is in the habit of using manure of some kind or other; he spreads over his land something which causes the plants to grow more vigorously, and yield him larger crops than he could obtain without it. A variety of different substances are used in different parts of the country to produce this effect; what then is the substance or substances which these different manures contain—and on what does their fertilizing power depend? Setting aside, for the present, the mechanical effects which many manures produce, and which are frequently very important, let us briefly inquire what is the composition of the ordinary kinds of manure. The great bulk of manure consists of decaying vegetable and animal matter, dead plants, and a variety of substances of vegetable origin, which, as they formerly constituted living plants, must necessarily contain those matters which plants require. When these vegetable or animal substances decay, for they are very similar in composition, they are in part dissipated into certain gases; there is left after the escape of these gases a quantity of dark-coloured charry-looking matter, which is comparatively unchangeable, and besides this there remains a small quantity of fixed earthy and saline substances, which all kinds of vegetable or animal matter contain. The chemical elements of ordinary manure are certain compounds of carbon, oxygen, hydrogen, nitrogen, and sulphur, and fixed salts.

The rotting of vegetable substances in manures is just the reverse of what takes place when plants grow, as they are gradually separated again into those very substances from which the plants were originally formed. In consequence of the many abundant sources of those gases, which form part of the food of plants, that exist all over the globe, it follows that the air always contains a small portion of them diffused throughout it, and hence plants can always obtain from it the gaseous substances which they require; nevertheless, as the quantity present in the air is always very small, the addition of manures, which yield more of these gases to growing plants than they could otherwise obtain, is always useful. With regard to the earthy and alkaline salts which plants contain, the case is very different; when we remove a crop, we take away a quantity of these salts, and the soil, of course, then contains less of them than it did before. There are not the same means naturally provided to restore to the soil these salts, as there are to restore to the air those gases which are essential to the growth of plants. It is true that fallowing does, to a certain extent, restore the soil to its original state, but without going into that subject, it is evident that it is even more important to supply saline, than gaseous matter to plants. Both are important elements of manure, but the former is the most important, because the natural means which exist for keeping up a regular supply of them to plants are less complete than those which regulate the formation and distribution of the gases.

The old chemists of by-gone times used to marvel greatly whence animals obtained the earthy substances which constitute their bones; it is now known that all animals which feed on plants obtain the phosphate of lime, which constitutes the greater part of bone, from plants. All plants contain phosphates of lime and magnesia, hence these are important constituents of manure.

The manufacture of pearlash and potash from plants has existed for a very long time. Plants are burnt merely for the sake of their ashes, which being rich in potash are valued as a source of that alkali. All plants contain alkali, either potash or soda; hence salts of these alkalies are constituents of many of the best manures; and the ashes of plants, rich in alkali, have always a beneficial effect when applied to land. The earthy phosphates and alkaline salts are the most important of the saline constituents of manure.

Looking at ordinary manures in a chemical point of view, we may divide them into those which supply the gaseous matters on which plants feed, those which supply alkaline salts and phosphates, and those which supply both at the same time. Farm-yard dung is of the best kind, and therefore it is adapted for all soils; it contains all that plants can want. Soot acts principally from the gaseous matters which it supplies to plants; whilst bones, and more especially burnt bones, may be taken as an example of a manure which supplies earthy phosphates.

Bearing these facts in mind, it becomes of the first importance to inquire what are the cheapest sources of these substances, and how they can be furnished to plants in the most economical and uniform manner.—*E. Solly.*

On the QUANTITY of SEED-WHEAT per Acre.

It is quite necessary for us to be acquainted with the habits of the plants we cultivate, before we can determine upon the degree of closeness with which they should stand together, so that, on soils of various fertility, the greatest crop may be obtained. Ignorance on this point leads to great error, as to the quantity of seed necessary on a certain extent of land. I have seen from three to four bushels of Wheat sown where three or four pecks would have been sufficient; four or five bushels of Barley sown where eight or ten pecks would have sufficed, and from six to seven bushels of Oats where only two or three were required. In this way a loss of a great quantity of seed is sustained by many farmers of the present day.

The crop of Wheat, I think, depends much upon the distance between the plants. In the experiments which I have made, I found that eight grains to a square foot was the quantity of seed which produced the best crop; these were planted three inches apart in rows six inches wide, and they produced from three to five large productive ears each, with scarcely any abortive ones. I found, also, that this quantity of seed yielded 28 to 38 productive ears per square foot, each ear thus having about four square inches to grow in. When more than this number grew on a square foot, some of them were abortive and many of them small; when a smaller number grew on that extent, they were long and coarse, there was a tendency to straggle over the ground, annual seeds sprung up, and the Wheat was more liable to disease, mildew, blight, &c. It may be said that 36 grains, each producing one stalk, might yield the same number of bushels per acre as the 8 grains which produce 36 stalks; but in the one case, each plant has only 4 square inches of ground for its roots to spread in—extending only 1 inch on each side of the plant, while in the other each plant has 18 square inches of ground to supply it with nourishment. In consequence of want of room the plants are unable to throw out offsets in the spring; the leaves being crowded, the straw gets soft and feeble, and ultimately becomes laid, and then yields a crop deficient both in quantity and in quality. Land that is in good condition always produces the best crop when the plants appear thin in spring. I have found a bushel of Wheat to contain 576,000 large healthy grains. This estimate was made from the red-straw-white Wheat, cleaned and prepared for seed, weighing 64 lbs. per bushel. Now, there are 43,560 square ft. in an acre, and multiplying this by 8, we have 348,480 grains, or 2½ pecks of Wheat, as seed sufficient for an acre of land. To this, however, should be added 1 or 1½ peck as the quantity which we may expect to be destroyed by birds, &c. We believe that if farmers were to reduce, on their good land, the quantity of seed Wheat they now use per acre down to 1 bushel, and if they were to dibble this in, their crop would be increased in productiveness.—*John Morton, Chester-hill, Stroud.*

COPROLITES.

Coprolites are supposed to be the fossilised excrements of animals, possibly of antediluvian origin. Many specimens exhibit on their surfaces convoluted marks or impressions, counterpart as it would seem to the internal surface of the intestine, and they are rounded off at the extremities in such a form as shows that they must have been produced in the manner alluded to. But if the external evidence upon this point be strong, that afforded by chemical analysis is conclusive. This reveals to us the fact of their entire coincidence in composition with fæces of animals now living, allowance being made for those changes which the lapse of so many ages must necessarily produce. We have in them the earthy phosphates in much the same proportion as they occur in bones, accompanied sometimes by organic matter, though at other times this seems to be wanting; this depending no doubt on the greater or less exposure to the action of the elements. The same circumstance is noticed with respect to fossilised bones, which, having been protected by a strong envelope from the causes of decay, have their organic matter (gelatine) intact, so that this may even be extracted as from the fresh bone, and soup prepared from these remains of a former world.

Bones, however, of far less antiquity than these, if exposed to the air and the action of moisture soon rot, as the farmer well knows; their gelatine being converted into gaseous compounds of carbon, hydrogen, oxygen, and nitrogen. The bones which are imported from abroad into the ports of London and Hull have lost much of their organic matter, so that their action upon crops must be attributed almost entirely to their phosphate of lime. This view is corroborated by Mr. Hannam's experiments on bones, burnt and unburnt, in which he obtained the same weight (within a fractional quantity) of Turnips from a quarter of each. Thus the opinion of Professor Liebig as to the vast importance of phosphates as a manure for the soil of Great Britain, is borne out by experiment, and it would appear that they are still more essential than even ammonia itself.

Coprolites then, if they could easily be had in sufficient quantities, and could be reduced economically to a fit state for the purposes of the agriculturist, would be to him a treasure indeed. I am sorry to say, however, that with Professors Buckland, Henslow, and others, I fear the sanguine statements on this subject, of the great German chemist, will never be realised.

The specimen upon which I operated was sent me by Mr. Deck, of Cambridge, a very clever geologist and chemist. He exhibited, in conjunction with Prof. Henslow (who read a paper on the subject), a number of Coprolites obtained from the Suffolk crag. They were found embedded in the cliff, at Felixstow, and numbers more were found mixed with the pebbles on the beach, where they had been exposed, as the rounded form bespeaks, to the same rolling process.

The Coprolites are then difficult to be distinguished by their external appearance alone, from the siliceous and other stones with which they are mingled. Of six or seven of these given to me by Coprolites, three

four were pebbles. By attention, however, they may be distinguished, even without breaking, by the pebbles being much softer to the touch than the true Coprolite: the latter, too, is much softer than the former. When broken, however, there can be no mistake, the Coprolites having the texture and colour of broken chocolate, and when rubbed violently they emit a peculiar smell, the intensity of which affords a criterion whereby to judge of the proportion of their organic constituents.

Prof. Henslow informs me that these Coprolites are the excrements of a fish of the shark species. Mr. Deck, in collecting them at Felixstow, found a fossilised bone, originally the internal ear of a whale. It is probable that the fish yielding the fossil excrement served as prey to this monster of the deep. I conclude by giving the analysis of these Coprolites:—

Earthy phosphates	56
Carbonate of lime	15
Matter insoluble in dilute muriatic acid	19
Organic matter and water inseparable at 400°	8
Water	2
	100

—*W. H. Potter, Fore-street, Lambeth.*

AGRICULTURAL EXPERIMENTS.

The argument by induction in favour of any particular manure must rest upon various and multiplied experiments, and those which I am about to detail serve to show into what serious errors we may be led by taking one or two alone for the basis of a general conclusion. Single experiments are only like straws thrown up into the air to show from what quarter the wind blows; they may be of use, to point out the course which should be pursued, but that is all the evidence they afford. It would be dangerous to infer that this or that manure is good or bad, because the one or the other may have succeeded or failed in some solitary trial. Thus, for instance, in the Journal of the Scotch Agricultural Society, Mr. Maclean has recorded the results of 28 trials of different manures as top-dressings upon Grass; two of them were salt and sulphate of ammonia, but with both of them only single experiments were made, and the conclusions to which they lead are directly the reverse of those to which my experience of them conducts me. With him, salt was the most successful of all the manures, and gave the largest increase of Grass; sulphate of ammonia was the least successful, with the exception of the muriate, and gave the smallest increase of Grass. With me, salt is useless, and sulphate of ammonia is very valuable when used in the right proportion. To ignorance of this proportion Mr. Maclean's failure may be ascribed; he used too much; for if I recollect right, he laid it on at the rate of about three cwt. per acre. His muriate of ammonia must have been applied in still greater excess; for there, and there alone, he suffered loss, the Grass being injured by the application. On the other hand, my failure with salt is no argument against its value as a manure in other situations; for it may be accounted for by my proximity to the sea. In any situation where the trees are killed or stunted in their growth by the sea-breeze, as they are here, in a south-west exposure on high ground, it is evident that the atmosphere must sometimes be saturated with muriate of soda, and probably enough of that material is thus conveyed to the grass. We must therefore bear in mind, not only that the failure of solitary experiments is not to be considered conclusive evidence against any new manure, but that even their success is to be distrusted till confirmed by repeated and various experience. Against the latter class of errors, however, I have no great reason to stand upon my guard; for all my single experiments proved signally unsuccessful. They were made with six different manures, and in all of them I have no doubt that the dose was too large. Two of them bear ridiculous names, and are very expensive; but that would be of little consequence if it could be proved that small quantities of them would more than repay the cost.

It will be seen that in two instances the application of the manure was injurious instead of beneficial; in one it was wholly inefficacious, in the rest the amount of loss is obtained by deducting the increased value of the produce from the cost of the manure upon an acre.

	Expense.	Loss.
I. 560 lbs. of urate	£1 0 4	£0 11 3
II. 32½ bushels of Clarke's desiccated compost, with 20 bushels of wood-ashes	3 13 7	2 17 3
III. 40 bushels of Poittevin's manure, No. 28, with 20 bushels of ashes	3 12 1	3 16 1
IV. 280 lbs. of oxygenated alkali, with 20 bushels of ashes	4 5 1	4 9 1
V. 280 lbs. of ammoniated alkali, with 20 bushels of ashes	6 5 4	5 16 10
VI. 28 bushels of Poittevin's, No. 176, with 20 bushels of wood-ashes	1 5 6	106 15 10

In the last instance the absolute neutrality of the application is so extraordinary, that, did I not know the very great care that was taken in conducting the experiments, I should be tempted to suspect that some error had crept into the account. Indeed, complete accuracy in these experiments is of so much importance, that before I proceed with the details of that more instructive series to which I have next to invite attention, I must explain the mode in which they were conducted. The produce per acre was computed from the trial of smaller quantities. A certain length of swathe on each plot of ground to which the manure was applied was measured and weighed both in the state of grass, and after it was made into hay; and this operation was repeated three times, and the mean of the results was then compared with the mean obtained from similar trials on the unmanured land adjoining. In estimating the value of the hay, it was taken at the then market price of 2*l.* 15*s.* per ton. Eleven experiments were tried with nitrate of soda, which in every instance increased the growth of the grass; but in no instance was that increase sufficient to reimburse the cost. The price of the nitrate was 1*l.* per cwt., and the value of the increase being deducted from the expense, gives the following table of loss sustained:—

I. 1 cwt.	£0	2	3
II. 1½ cwt.	0	10	9
III. Do. in another place	0	11	9
IV. Do. do.	0	2	6
V. 1½ cwt.	0	7	6
VI. 1 cwt., 16 bushels of wood-ashes, and 2 of salt	£1	2	11
VII. 240 lbs.	1	11	4

In the two last instances the land was in better condition, and might seem not to want manure at all, for without any it yielded more than two tons of hay per acre. It is to be observed that where the smallest quantity was used, the loss, too, was the smallest; and it is evident that if only a small proportion of manure is needed to supply the grass with the nutriment of that sort which it requires, every addition of it beyond that proportion must be expended in vain, for the action of frequent rains would not allow it to remain in the soil stored up for future use. Perhaps 50 or 60 lbs. would have produced the same effect as a larger quantity, and then there would have been, in the two last instances, a clear profit of about 7 or 8 shillings. The same conclusion is very strikingly indicated by the experiments with sugar scum, an article much used in France in the cultivation of the Vine, and imported for the vineyards at considerable expense. Its cost to me was 1*l.* 5*s.* per ton. The application of it invariably produced a greater quantity of hay, but almost in an inverse proportion to the quantity employed; there can be no doubt, therefore, that it is beneficial as a manure on grass, if only the right proportion can be discovered; but it must be owned that the admixture of a small quantity of wood-ashes in each case keeps its own specific virtue somewhat in the dark. The cost of the wood-ashes is estimated at 4½*d.* per bushel.

	Increased value of Hay.	Gain.	Loss per Acre.
I. 24 cwt. and 8 bushels of ashes	11*s.* 3*d.*	—	£1 6 9
II. 20 cwt. and 8 do.	8 6	—	0 19 6
III. 16 cwt. and 8 do	14 0	—	0 14 0
IV. 12 cwt. and 4 do.	14 0	—	0 2 6
V. 8 cwt. and 4 do.	14 3	—	0 0 3
VI. 8 cwt. and 4 do. in another field	14 3	2*s.* 9*d.*	0 0 0

In the last case the land was poorer than in the preceding, the produce of Hay per acre in the adjoining unmanured part being 1 ton 12 cwt. 34 lbs.; whereas in the other it amounted to 2 tons 3 cwt. There was also a great difference between the 1st and 2nd experiments in the quality of the land. On the first the quantity of hay without the manure was only 15 cwt. 50 lbs., while the other produced without manure 2 tons 6 cwt. 28 lbs. It thus appears that sugar-scum is most effective where manure is most wanted. It is a great mistake, however, to suppose that the more you use the more you will get from it, for the maximum of produce was obtained from the smallest quantity. It remains to be tried whether a still smaller quantity may not produce the same effect; and whether, under any circumstances, it benefits the succeeding crop. At present there is no great encouragement to persevere in its use as a top-dressing for Grass. The experiments with guano were more successful; but though up to a certain point an increased quantity of manure gave an increased quantity of produce, yet they still bring us to the same conclusion, that, as the proverb says, too much of anything is good for nothing. The cost of this manure was 12*s.* per cwt.

	Increased Value of Hay.	Loss.	Gain.
I. 3½ cwt. and 20 bush. of ashes	2*l.* 2*s.* 9*d.*	—	£0 1 4
II. 3½ cwt., 1 year old, and 20 do.	1 11 5	16*s.* 0*d.*	—
III. 3 cwt. and 1 cwt. of nitrate of soda	2 0 4	15 8	—
IV. 2 cwt. and 4 bushels of ashes	3 0 7	—	2 15 1
V. 2 cwt.	1 15 9	—	0 11 9
VI. 1½ cwt.	1 13 9	—	0 12 9
VII. 1½ cwt.	1 4 5	—	0 6 5
VIII. 1 cwt., 6 bushels of salt, and 16 bushels of ashes	0 5 8	18 0	—

In the last instance, it may be that the soil was almost saturated with as much nutriment as the Grass required; for its produce without any manure amounted to 2 tons 7 cwt. 90 lbs., and thus 18*s.* worth of the manure produced no effect at all. The contrary fact will account for the great success of the 4th experiment, for there the weight of hay on the unmanured part was no more than 12 cwt. 34 lbs. From a comparison of the two first it appears that guano loses much of its efficiency by being kept, its volatile parts being dissipated in the air, and that even the best, applied to good land in large quantities, will not yield any adequate return. The weight of hay in this case, without the manure, was 2 tons 1 cwt. 70 lbs. From the experiments upon sulphate of ammonia it is not so easy to deduce any certain conclusions, some of the results being very anomalous. The moistness of the spring was favourable to its action generally; but as it was not all laid on at the same time, the fact of the weather being different at different times may account for some of the variations. The cost was 17*s.* per cwt.

	Increased Value of Hay.	Loss.	Gain.
I. 336 lbs. sown at thrice	2*l.* 0*s.* 3*d.*	10*s.* 8*d.*	—
II. 224 lbs. from the bottom of the cask	2 0 3	—	£0 15 9
III. 224 lbs.	2 18 0	—	1 4 0
IV. 168 lbs. sown at thrice	1 6 0	—	0 0 9
V. 120 lbs. sown at thrice	0 14 4	3 10	—
VI. 120 lbs., and 4 bush. of ashes	2 0 4	—	1 2 11
VII. 80 lbs.	0 11 3	0 11	—
VIII. 73 lbs. and 640 gallons of drainings from the farm-yard	2 3 0	—	1 17 0
IX. 64 lbs., and 4 bush. of ashes	1 14 0	—	1 4 0

It is remarkable that in two out of the only three cases, where the application was made at two different times, loss ensued, and in the third a very insignificant profit. In the other case of failure, the land produced 2 tons, 4 cwt. per acre, without manure. The second and third experiments seem to show that on poor land as much as 2 cwt. may be usefully employed; for in the former case, the unassisted land yielded only 15 cwt. 32 lbs. of hay; and in the latter, 10 cwt. 22 lbs.; but that 3 cwt. is too much is the only inference to be drawn from the first, for there too the natural produce was only 10 cwt. 105 lbs.; in all the rest it exceeded 2 tons. It will also be seen that in the two last experiments, where the quantity used was smallest, the profit was largest. It will be a pleasant doctrine for farmers if it can be proved that the less expense they incur in the use of an artificial manure, the larger profit they will gain; and this rule, it seems, applies equally to a temperate use of their own farmyard manure; for two portions of equally good land being watered with drainings,—the first once, and the second twice—the first gave an increase of the value of 11*s.* 4*d.* above the adjoining land; the second fell below it nearly to the same amount. Some uncertainty, however, attends this experiment, because the liquid may not in both cases have been of equal strength.—*L. Vernon Harcourt, Westdean House.*

(To be continued.)

ON MINERAL & INORGANIC MANURES.—No. I.

By Professor Charles Sprengel.

(Translated from the German.)

It has been previously observed that the substances used for manures are composed of earths, oxides, alkalies, and acids, and that the last mentioned occur always combined with the first into salts.

Although agriculturists make now-a-days far more use of mineral manuring substances than in former times, having become convinced that they take as active a part in the nourishment of plants as organic manures do, still several, which besides those hitherto used may be of avail, have been as yet entirely neglected. The cause of this neglect probably rests on the insufficient knowledge of mineral manures, as most believe that they only act by improving the texture of the soil, or that they promote vegetation merely by dissolving the humus; so fine, that they are only so far useful as they enable plants to a more energetic vegetation. It may, however, be now assumed with certainty, that they are a real food of plants, and as essentially necessary to their constitution as the oxygen, hydrogen, carbon, or nitrogen contained in the organic manures. It is not less true, that in this mistaken view of the action of mineral manures, many real advantages have been hitherto sacrificed, because the culture of plants would have been carried on more effectively, if the principle had been acknowledged that plants have to obtain a necessary quantity of these mineral substances from the soil which are found in them by chemical analysis. Even the phenomenon that on each kind of soil some particular tribe of plants will loose itself spontaneously, ought to have led the farmer to an opinion different from that hitherto entertained. Every soil, for instance, will produce other plants than marl, and this again other than a peaty soil, &c. Thence we may learn that the growing of plants is dependent, generally speaking, on certain mineral substances contained in the soil, and that it is working in opposition to the very nature of crops to plant them in localities, where (according to their chemical constitution) it is impossible for them to grow. We find every day that many wild plants only come up in spots where the soil abounds in potash, or gypsum, common salt, manganese, &c.; and why should we doubt that cultivated plants, also, must find some particular mineral substance abundantly in the soil where they are found to grow luxuriantly? According to the opinion of several Naturalists, carbon, hydrogen, oxygen, and nitrogen alone constitute the proper nourishment of plants, so that if mineral substances occur in them, they are to be considered merely accidental. But with the same plausibility it might be assumed, that nitrogen, &c. are the merely accidental ingredients of plants, and that the minerals are their real nourishment.

Some others assert that plants possess the power of forming the mineral substances which they contain out of carbon, nitrogen, &c., transforming them by their vital powers into mineral substances; and they refer to some experiments made long ago; but, as it can be proved that these have been made very imperfectly, they do not deserve any credit, and though they were worthy of confidence, they do not prove what it is intended they should. Very lately, a believer in this doctrine of the nourishment of plants asked the following questions (*vide* the preface to "Schübler's Agricultural Chemistry," 1838.) "How is it, that after 100 crops reaped on the same soil, there are found in it not only traces, but ½, ¼, and even entire grains (per cent.) of certain salts? or, how is it, that on average calculation, the corn crops of 20 years contain in their grain and straw more phosphate of lime than any soil in the world contains? for phosphate of lime is nowhere an original constituent of the soil." The same author says, further, "If Hermbstädt obtained 936 lbs. of calcined potash, from 2361 lbs. of the common Mugwort, (which he grew on 18,000 square feet of a sandy soil), each cubic foot of the soil must have contained more than 340 grains of potash for the use of the plants. But as this could not be assumed to be the case with the arid sandy soil of Berlin on which Hermbstädt made his experiment, the great amount of potash in the plants is to be ascribed to their luxuriant vegetation, not to the composition of the soil." To this I reply: According to several of my experiments, made with great accuracy, several, even sterile soils, which have never been manured with dung, and where, consequently, the constituent substances were originally inherent in the soil, contain 1—2

per cent. of phosphate of lime. Now, as the Magdeburg acre of land contains 25,920 square feet; as, moreover, the roots of corn penetrate at least one foot in the soil, and as the Rhenish cubic foot of earth weighs (at an average) 100 lbs., the plants of one acre will have 25,920 lbs. of that substance to absorb, though the soil only contained 1 per cent. of the phosphate of lime. But the Wheat crop of one acre of land contains at the utmost only 5 lbs. of phosphate of lime; and consequently the 25,920 lbs. will suffice for 5187 Wheat crops; nay, though the soil contained only $\frac{1}{100}$ per cent., there would be enough of it for 52 Wheat crops. The Barley crop of one acre contains about 6 lbs. of phosphate of lime, and therefore 4320 crops would be nourished by the same amount of phosphate. A crop of Oats, grown on one acre, contains 5 lbs. of phosphate of lime, consequently 5187 crops will find a sufficient amount of the above mineral substance in the soil.

It is true that it cannot be assumed that the corn will be able to abstract from the soil even the least particle of phosphate of lime, still this calculation will fully prove, that the assumption of the author of the above work, viz., that 80 corn crops will abstract from the soil more phosphate of lime than any soil can possess, is utterly unfounded. The same is the case with the potash, which the plants are said to generate in themselves by their luxuriant growth, the most accurate examination of several very sandy soils and subsoils having shown to me, that they often contain $\frac{1}{10}$—$\frac{1}{15}$ per cent. of potash. This potash was not combined with any acid into a soluble salt; on the contrary, it was always combined with silica into a silicate insoluble in water; but as this is gradually dissolved by the carbonic acid contained in rain-water, (carbonate of potash, an easily soluble salt, being formed,) the roots are able to provide themselves constantly with the necessary amount of the alkali. By this wise arrangement of nature, the silicated potass of the subsoil has nourished for thousands of years the deep-rooted plants; and considering the amount contained in the lower strata of soil, there is no doubt of its being yet sufficient for many centuries to come. The roots of Mugwort penetrate four feet deep in the soil; therefore it may on one acre of land draw upon four times 25,920: viz., 103,680 cubic feet, or 10,368,000 lbs. of soil. According to experiment, 100 lbs. of earth contain on an average one-third per cent. of potash; consequently the Mugwort found on the area of one acre of land 20,736 lbs. of potash, from which it might well receive those 936 lbs. or more of carbonate of potash. I may as well mention that I never subjected the subsoil of Berlin to chemical analysis; but I have examined similar soils of the diluvian formation, and have often found more than one-fifth per cent. of potash in them. These calculations, I think, prove that the power which has been attributed to plants of forming substances within themselves, is based on erroneous suppositions. We often do not believe that soils contain the mineral substances which we find in the plants growing on them, and yet an accurate analysis shows afterwards that they are abundant. Still at times the soil contains scarcely a trace of those substances of which the plants are composed; but even in this instance it is not necessary to assume that they are formed by the plants, as we shall see hereafter that the rain conveys annually more than 50 lbs. of earths and salts to the soil of one acre.

(To be continued.)

Home Correspondence.

The Berberry Blight.—It is somewhat remarkable that both persons and plants will get characters frae the world that they dinna deserve. The Berberry, I think, has come in for a sharé o' muckle abuse that it dinna merit. I mind fu' weel when I was a young callant o' wandering frae home ae day, and in my wanderings came upon a large Berberry-bush wi' plenty o' ripe fruit on it; I partook o' the fruit, and also broke off some o' the branches that were well laden, to carry them hame. Before I reached my father's house I was met by an auld woman who was looked up to by her neighbours for her superior knowledge; she saw the fruit I was carrying, and speered gif I had eaten ony o't. "O, ay," says I, "a wamefu' o't." "Weel, weel, my man, ye hae been eating pousin, and ye'll may be no live lang." I canna describe the feeling that came o'er me at sic an announcement; I was instantly placed under medical treatment, and forced to drink wonderfu' draughts o' buttermilk to conteract the evil effects o' the Berberries, besides receiving a lecture about going to the Berberry-bush, as if it had been the fabled fatal Upas-tree; and to this present hour the ideas o' Berberries and buttermilk are often associated in my mind. But as Mr. Wighton wishes to ken the reason why the Berberry is blamed for having an "evil influence upon Corn," perhaps some o' the following statement may satisfy him as a reason why it is blamed. In the "Quarterly Journal o' Agriculture" there is an article "On Wheat, Canker, and Rust or Mildew;" and it is there stated that, "in consequence of the leaves of the common Berberry exhibiting a similar affection to the rust in Corn, farmers, both in England and on the Continent, have concluded that the infection spreads from the bush in the hedge to the Corn in the field; and this notion is sometimes strengthened from the rust appearing in patches and stripes among the Corn, as if it had been carried thither by the wind from the Berberry-bushes." Now there was once a learned gentleman wha had some o' his Peach-trees trained over the tap o' his garden-wall, wi' their points towards the antipodes; he also wrote a treatise "On Blight in Corn;" and appeared to countenance in some degree the popular belief respecting the evil effects o' the Berberry on Corn. He tells about "Mildew Holesby, in Norfolk," what an unco' place it was, where Berberry abounds and Wheat seldom succeeds! and we are informed, in the "Library o' Entertaining Knowledge," vol. ii., "that the fructification of the Berberry is incomplete unless the stamens be irritated by insects, when the filaments suddenly contract in a most remarkable manner towards the germ; the flowers are therefore, by a beautiful arrangement of Nature, peculiarly attractive to insects, and thus the Berberry may become injurious to neighbouring plants." And we are also informed by the Rev. Dr. Singer that the views of Sir Joseph Banks, and of some intelligent practical farmers relative to the evil influence of the Berberis vulgaris, induced the late Admiral Sir William Johnstone Hope to give orders for the total extirpation of the Berberry-bushes which intermixed with thorns in the hedge-rows; and since that was done, and for above 20 years, no such distemper has appeared in the fields. But for a' that, there are some auld farrant chells, if they get a few facts to stand by, they are just as stiff as the facts themsels, and they will not believe in the popular creed, although it should be supported by knighted philosophers or presidents o' the Royal Society, or preached up by reverend divines; and as lang as the twa-celled Puccinia graminis differs frae the pustulated Æcidium berberides they will not believe. De Candolle opposes the notion that the Berberry is injurious to Corn, and says that he should not have agitated the question, had it involved a plant less important than Wheat, or a philosopher less distinguished than Sir Joseph Banks; and Dr. Greville, when speaking of the Berberry Blight in his Scottish "Cryptogamic Flora," says, "This minute gastromycus has given rise to the vulgar opinion that the neighbourhood of Berberry-bushes is extremely detrimental to fields of Wheat. It is well known that the disease called the rust in Corn is highly injurious; but the colour of the rust and that of the present plant constitutes the only similarity between them. They belong, in fact, to two different genera, and of course cannot propagate each other." And gif ony o' the readers o' the *Chronicle*, wha tak an interest in such a subject, should turn to the ninth volume and 327th page o' the "Gardeners' Magazine," they will find "Notes on Mildew, from a Lecture by Professor Lindley;" they will there see figures of the different fungi that will, maybe, convince them sooner than a' that can be said about it for a lang time; and I may just conclude this notice by a quotation frae "Paxton's Horticultural Register" on the same subject, the writer says that "it would be no less rational to maintain that a field of Wheat would spring up if we should sow Berberries, than that the rust growing on these should produce the Corn-rust. Should it be said that it is the difference of the nutriment of the fungus which causes the difference, I should ask whether a difference of soil would produce Rye on Oats when Wheat-seed only had been sown?"—*A Moorland Gardener.*

Experiments with Manures.—Table shewing the quantities and cost per acre of Five different Manures used in a field of Mr. A. Bubb's at Witcombe, in Gloucestershire, and their relative effects on the quantity and quality of a Wheat crop, as compared with that in the same field where no manure was used. The Wheat is valued at 6*s.* a bushel, and the straw at 40*s.* a ton. The proportions of salt and lime were, salt 1, lime 2.

Manure used.	Quantity.	Cost.	Produce.	Value of Produce.	Profit or loss on Manure.	Weight of best Corn.	Weight of Straw.
		£ s. d.		£ s. d.	£ s. d.		
None .	.	.	Best Corn 29 1 0 } Tail ditto 0 1 0 }	10 16 8	.	61¼ p. bush. lbs.	lbs. 3858
Nitrate of Soda . }	1 cwt.	1 2 6	Best Corn 36 0 0 1 0 } Tail ditto 0 1 0 }	10 16 8	Profit. 0 19 8½	61¼	4824
Kiln Dust . }	40 bushels	1 0 0	Best Corn 30 3 0 1 0 } Tail ditto 0 3 0 1 0 }	9 3 6	Loss. 0 14 1½	61¼	4068
Lime and Salt . }	60 bushels	1 5 0	Best Corn 33 0 0 3 0 } Tail ditto 0 1 0 3 0 }	9 13 1½	Loss. 0 10 6½	61¼	4068
Urate .	6½ cwt.	1 19 0	Best Corn 27 3 0 2 0 } Tail ditto 0 3 0 2 0 }	8 7 3½	Loss. 2 13 4½	61	3672
Guano .	2 cwt.	1 6 .	Best Corn 33 0 0 3 0 } Tail ditto 0 3 0 3 0 }	9 13 7½	Loss. 0 10 6½	61	4248

The soil is sandy and of good quality.

Ravages of the Slug on the Wheat Plant.—As the ravages which Slugs make amongst young Wheat renders the adoption of any method likely to destroy them a great boon to the farmer, I may perhaps be allowed to state that the most effectual way, where good stone lime cannot be had, is to scatter a number of Cabbage-leaves over those parts of the field which is worst affected, and let a number of boys or women look over them every fine morning, and pick off what may be attached to each leaf. I dare say the plan is pretty generally known and adopted amongst gardeners, but some farmers may hesitate about it on the score of expense, yet is it not nearly so expensive as many would suppose; and when the land is tolerably good it well repays itself. I may add that slices of Swedish Turnips do as well as Cabbage-leaves, and even the tops may be used also, or anything likely to be attractive to this destructive pest.—*S. N. V.*

Cultivation of Wheat.—The following calculations were made from Wheat grown in the year 1843, on land in my occupation belonging to Sir Oswald Mosley, Bart., situate in the parish of Tutbury, Staffordshire.

Description of Wheat.	Cultivation.	No. of bushels per acre weighing 63 lbs. each.	Weight of Straw per acre.	Average Weight of Corn per Imperial bushel.
			cwt. qrs. lbs.	lbs.
Red	Drilled in	29½	31 2 6	66½
do.	Ploughed in	28½	31 0 23	64
do.	Harrowed in	33⅓	36 3 4	65½
White	Drilled in	29½	29 3 22	64½

—*William Cox.* [It is not stated from what extent of land these calculations were made; but we do not think the differences between the several cases greater than may be accounted for by variety of soil, or than probably would have appeared on the same plots though they had all been cultivated alike.]

Corn Weevil.—A correspondent of the *Chronicle* complains of the depredation committed in his malt stores by the Weevil. About 15 years since Messrs. Fison, of Thetford, suffered greatly by this insect. They destroy the farina, leaving the husk, to all appearance sound, except at that end where it gained admission; after several ineffectual attempts to get rid of them they determined to try fire, which proved perfectly successful. It was applied thus,—a large quantity of furze was procured, the premises were emptied, and they were fired on the floors; plenty of help was provided, so that once kindled it was continually stirred about to prevent the premises taking fire. I have no doubt a better plan would be to fumigate them with sulphur. A dish of charcoal, with one or two pounds of sulphur, and the windows and doors well closed, would be all that is required, and the expense less than half-a-crown.—*James Fison.*

Reviews.

The Economy of Farming; from the German of Prof. Burger. With copious Notes from the Works of Thaer, Sprengel, &c. By E. Goodrich Smith. Wiley and Putnam. 8vo, pp. 132.

THE causes on which any agricultural fact or appearance depends are very many and variable. This renders it difficult for individual farmers, though examining the results of *their own* experiments, to determine what portion of them may be considered as owing to the causes which they had put in action, and how much is due to the natural causes over which they have no control. How much more difficult, then, must it be to determine the real meaning and value to be attached to reports of experiments, when the results, indeed, are given, but only some of the agencies described of which they are the consequences. In fact, in a country like our own, covered by such various soils, and experiencing such variable and various climates, were there not a way of subtracting from the results of agricultural experiments, that portion of them which is owing to the external circumstances of the several cases, reports of such experiments would be valueless, except in the immediate neighbourhood of their trial.

The method alluded to consists in gathering together a great many experiments on one subject, performed under every possible variety of circumstances, and taking their average result. Such an average will, in all probability, be the proper effect of the artificial cause, whatever it may be, that was put in action. For all the variable natural causes, in the comparison of a number of cases in which they pull in opposite directions, will be found to neutralise one another. And thus it is that the remark made by the Hon. and Rev. L. V. Harcourt, in his report of experiments with manures, which will be found in another column, is true of almost every question in farming, that a great number of facts are necessary as the foundation of a conclusive argument on the subject.

These observations are suggested by the perusal of Prof. Burger's work on "the Economy of Farming." We have nowhere seen such a great body of facts collected together, bearing on the subjects treated of. We call them *facts*; they are reports of experiment and observation made in many different quarters; and though individually such reports are to be received with distrust, yet a great number being collected, the average result may reasonably be regarded with confidence.

The subject of this work is necessarily of primary importance to the practical farmer; it is with him the only test which determines the value of any proposed improvement on his practice, however beautiful in other respects the proposal may be, and "the economy of farming" ought therefore to be the object at which all agricultural writers should aim.

The object of the good farmer is to produce order, cleanliness, and fertility, where his unskilful predecessor had left all in confusion, not because these are things desirable in themselves, but because they are means to a profitable end; for as Professor Burger states at the commencement of his work:—

"The object of farming is that of all kinds of business, viz., by means of labour and money, judiciously employed,

to produce gain, or to acquire money:—in other words, for one so to employ his labour and capital as, by the management of his affairs, to secure the highest income."

Professor Burger divides his subject into two branches. The first refers to "the outer household affairs," as, in common with other portions of the work, it has been somewhat too literally translated, and includes within its range all matters connected with labour and manure. The second refers to "the inner household affairs," the Domestic Economy, in fact, of the farm; and under this head are considered the arrangement and distribution of labour, the duties of employer and employed, and the mode of keeping farm accounts.

Every plan or practice suggested or described under these heads is referred to its ultimate expense or profitableness, for the real character it must hold in the eyes of the practical farmer. Thus, to take the subject of manure, after a general statement of what that is which constitutes manure, Professor Burger considers—

1. How much is needed to retain a given extent of land in fertility? And this, being dependent on the character of the soil and that of the crops grown on it, is answered in great detail with reference to both of these particulars.

2. What animals produce the necessary quantity at the cheapest rate? and, as affecting this, the effect of the character of the fodder on that of the manure produced by its consumption is taken into account.

3. What number of animals are thus required?

4. What weight of manure is obtainable from the consumption of a given quantity of a given kind of fodder?

5. What proportion, on a farm, must the production of plants for sale bear to the production of plants for fodder?

6. What rotation of crops must be adopted, in order that, on a given extent of land, the supply of manure from the manure-producing crops may be suited to the wants of the exhausting crops, so that the land be not gradually deteriorated?

The answers to all these questions are illustrated and enforced at great length by the details and results of numerous observations and experiments; and putting out of sight the admirable arrangement of the subject, the "Economy of Farming by Professor Burger" would be a most valuable addition to our agricultural library, were it only on account of the number of facts and experiments recorded in it. Many of these, it should be stated, are introduced in the form of notes, and are extracted from the works of other German writers of high repute.

In conclusion, we extract from the translator's preface the following paragraph, from which the general character of this work may be gathered:

"The great distinction in German Agriculture, compared with our own, is *economy*. The question is not whether a great crop *can* be produced, or a fine story can be told, what large animals can be raised, &c.,—but what is the whole cost, the expenditure of labour, of land, of manure, &c. For this reason computations have been made, and the proportion of all the parts and processes has been fixed. Economy compels them to weigh and measure their fodder. The minutest details have been entered into, the most difficult points examined, and the results brought out."

Miscellaneous.

Improvements in Wigtownshire.—We proceed to give some account of improvements made by Lord Stair, on his Lordship's home farm, Culhorn, Wigtownshire. We call public attention to the subject to show that all circumstances—natural disadvantages, soil, climate, and outlay—being taken into account, the improvements at Culhorn are encouraging and important to the community, and exhibit results interesting and advantageous to the Agricultural world. In calling attention to Lord Stair's improvements on his home farm, all acquainted with Wigtownshire during the last three years, will understand that we circumscribe ourselves to a narrow spot in the wide field of improvements which have been executed at so much expense by his Lordship, by thorough-draining, fencing, &c., since he succeeded to his extensive estates in Wigtownshire. The portion of Lord Stair's home-farm, now alluded to as under improvement, may be stated at 150 acres, composed of the following inclosures:—1st, Borland moss; 2d, Glenhapple; 3d, Fleming Park; and 4th, Craignerks. There was a good deal of work to be done on the farm, first in cutting large channels into which to take the main drains and water from the various fields, grubbing of trees, levelling of old mound fences, repairing of roads, &c. Prior to these operations, the fields alluded to had been grazed with cattle, so far as was safe and practicable. The first field which we shall consider—Borland Moss and Cowpark, 16 acres in extent—was altogether a morass, and part of it had been cut over for peats for the previous 30 years. This was certainly the roughest and most unmanageable of all the fields taken as a whole; but still in a large proportion of the other fields much swampy, and to all appearance worthless, ground presented itself, rendering draining most difficult, and furnishing little available soil even when dry. Good working, top-dressing, and manuring, however, has made a great change even upon this ground. Borland Moss was commenced to be drained in autumn 1840, with drains 15 feet apart, 3½ to 4 feet deep. Wooden soles were used, and a quantity of brushwood covered in above well-burned tiles. The draining completed, next came the paring and levelling of its rugged peat-cut surface. This was partly done with the plough, where the ground admitted of it, and partly with the paring spade; all refuse turf, brambles, and heath being collected in heaps, burnt, and the ashes spread on the surface. The field got dry and was ploughed and sown with oats in spring 1841, yielding that year, though wet and unfavourable, an extremely heavy crop of straw, and, even as regards grain, fully an average crop, of the growth of the district. After harvest the stubble was heavily top-dressed with sand and gravel taken from a bank in the upper side of the field; this was ploughed in and lay till spring, when the ground was well worked, limed at the rate of 90 bushels (price 37*s.* 6*d.*) per acre, and the field was then manured for turnips as follows:—About 10 acres received 30 single cart-loads of good farm-yard dung per acre, sown with Swedish Turnip-seed, the remainder got 15 such cart-loads and 15 bushels of bone-dust per acre, sown with Dale's Hybrid. We saw the crop, which was excellent. Indeed we do not think that a better crop was grown on any soil in the South of Scotland last year. Many of Laing's purple-top Swedes, when cleaned and the top and root cut off, weighed upwards of 15 lbs. weight. This year's crop of oats on the same field was too luxuriant, as a considerable portion lodged with the heavy rains and did not quite fill; but still good judges estimate the gross produce of Borland moss, white crop 1843, at between 50 and 60 bushels per acre, besides a very heavy yield of straw. 2. Next—Glenhapple, containing 56 Scotch acres—commenced also in 1840. More than a third of this was bog and quagmire like Borland moss, and a great part, even where ploughable, soil of a very poor kind. About one-third was thorough drained,—the field was levelled like the first mentioned, and sown with oats in 1841. The crop was very fair in the greater part of the field, but inferior in some thin parts which had formerly been soured with water. In autumn and winter the moorish parts of this division were well top-dressed with gravel and other stuff, and another oat crop taken in 1842, which was excellent, the quality of the oats being upwards of 40 lbs. weight. This field was well worked for turnip-crop 1843, and manured with from 25 to 30 cart-loads of ordinary farm-yard dung, together with 25 bushels of bones, or 3 cwt. of guano per acre. The crop is an excellent one of all kinds, healthy, thick, and will feed well. Third field—Fleming Park—about 37 acres; 20 acres drained, of which 8 acres were very bad moss, white running sand below, and most difficult to drain. Crop of oats 1842, good; and this year, after a proper top-dressing of compost, with lime and ditch-cleanings, this field also yielded a very good crop. Fourth field—Craignerks—38 acres, formerly a wet rushy pasture field, but of very unequal nature and quality—though, on the whole, in better state than the other fields—all thorough-drained, and sown last spring with oats: the crop was a very superior one. In executing the improvements on Culhorn farm, a strict regard was paid to efficiency combined with economy,—every operation was entered upon with the view of obtaining a profitable return for the outlay; and how far this object has been realised, the following abstract statement of expense of improving the four divisions of the farm formerly mentioned,—the aggregate amount of produce of crops 1841-42, and 43,—the actual rent previous to improvement, and the present estimated value of these lands, will sufficiently testify. The expense of improvement will stand thus:—

	£	s.	d.
Draining, say 94 Scots Acres with tiles, from 4 feet to 2½ feet deep, being at the rate of about £7 16*s.* 1*d.* per acre	733	19	3*d*
Expense of sinking the course of the stream for outlet to drains	24	8	6½
Paring and burning, and levelling old fences	61	6	5
Grubbing trees, whins, &c.	62	12	3
Erecting division and road fences	64	19	8
Making roads for use of farm—about	30	0	0½
Total expenditure in permanent improvements	£977	6	2

Crop of last three years stands thus:—1. The oat crop in Borland Moss, and Cowpark, and Glenhapple, in 1841—together, 72 acres—amounted to 244 bolls of 12 Winchester bushels, or at the rate of 40 bushels per acre; weight, 39 to 40 lbs. per bushel. 2. In 1842 about nine acres of Borland Moss and Cowpark were sown with turnips, as previously mentioned, the produce of which amounted to about 40 tons per Scotch acre. The remaining seven acres were planted with potatoes,—produce, 252 bolls of 8 cwt., or at the rate of 576 bushels per acre. This was a very extraordinary crop; and, considering the worthless state of this field prior to improvement (only grazing two cows and their calves, though 16 acres in extent), went far to liquidate the expense of improvement—if, indeed, it did not reimburse the whole. The second crop of oats from Glenhapple, 1842, and first from Fleming Park—together, 93 acres,—amounted to 486 bolls, or at the rate of 62 bushels per acre; weight fully 40 lbs. per bushel, besides 32½ bolls of inferior grain. 3. The turnip crop in Glenhapple Park, 56 acres, this season, 1843, is altogether very superior, and the actual weight of the fourth part of an acre which has been taken up, and cleaned of top and root, amounted to 8½ tons (and the crop is equally good throughout the field), thus giving a produce of 34 tons per acre. The quantity of manure applied to this field, per acre, as noticed in the preceding part of this report, may appear extravagant, but we would beg to explain that the quantities stated were applied only on such parts of the field as had not at any former period been under cultivation,—the other portions of the field receiving, per acre, about 16 cartloads of dung, with 3 cwt. of guano, or 25 bushels of bones. The annual rent realised from these 147 acres of Culhorn farm previous to improvement amounted only to 112*l.*, or, on an average, a fraction more than 15*s.* 2*d.* per acre; and we are sure that in estimating the present value at 30*s.* per acre, notwithstanding the current agricultural depression, we are rather within the mark than otherwise. We make these general remarks merely to show agriculturists what can be done by a judicious outlay of capital on a naturally poor, barren soil; and we hope the time is not distant when the intelligent and enterprising tenants, as well as landlords, of Wigtownshire, will find it their interest to apply their spare capital and well-directed energies to the improvement and better cultivation of their farms—thus rendering themselves the benefactors of the district in which they live, by the additional employment thereby given to the labouring classes, who would consequently be enabled to live better and educate their children. We have been led to notice the improvements on Culhorn farm entirely from their being so conspicuous. But as we have already noticed, these are only a speck in the wide field of agricultural improvement entered upon by Lord Stair. His Lordship has land in fourteen parishes out of the sixteen which compose the entire county; and ever since his accession to these estates, the leading operations of permanent improvement—erecting farm-houses and making fences and drains—have been in rapid progress over the length and breadth of his possessions. There are two extensive tile-works on his Lordship's estates—one at the upper, the other at the lower end of the county, at which there are made annually about fifteen hundred thousand drain-tiles, besides a corresponding quantity of soles. Since spring 1840, there has been made at these works, and used on the estates, the enormous quantity *of three millions one hundred and sixty-four thousand five hundred and twenty-eight drain-tiles*,—these tiles are each fourteen inches in length; and when we apply the foregoing quantity in lineal measurement of drain finished therewith, we bring out a total of upwards of *six hundred and ninety-nine miles of drains*,—besides many miles that have been finished with broken stones previous to the erection of the second tile-work; and all this within the *short space of three-and-a-half years*. Lord Stair has thus not only set an example to his tenantry and the agricultural district at large, by the recent improvements on his home farm, but in the spirit of genuine liberality has kindly placed within the reach of his tenants, great and small, an opportunity of experimenting for themselves. Three experienced drainers have very properly been selected and placed in different quarters to take the entire management of the drainage on the estates—not leaving so important an operation to uncertainty, or to individual caprice or fancy, but securing what is both necessary and prudent, the proper execution of the work. The practice on the Stair estates therefore is, that the proprietor pays the whole expense of the drainage and charges 5 per cent. per annum on the outlay. The great work of a better system of husbandry has thus been laid by Lord Stair for his tenantry; and it is particularly gratifying to see the happy results of such a course in the more extensive green crops now cultivated,—and these certainly of a decidedly superior quality to what could be formerly raised under any management however good. [The Scotch acre alluded to above is ¼ larger than the Imperial acre.]—*Wigtownshire Free Press.*

The Duke of Cleveland on Leases.—At an agricultural meeting the other day, the Duke of Cleveland said, within three miles of the place where he had resided for the last nine years was a place which had long been rented as a rabbit warren; a spirited farmer acquainted with it applied to Sir William Welby, and said if he could have a lease for 14 years that he would break it up and bring the land into cultivation, his rent being allowed to remain at the same amount as that paid by the warrener. This offer was accepted, and the farmer being satisfied that the undertaking would ultimately repay him, entered with spirit upon it. In the fourth or fifth year after the warren was broken up, he (the Duke of Cleveland) saw this farm, and he could testify that it was bearing the best crops in the county; and last year, in the month of July, he again saw it, and would not wish to behold finer crops of Wheat, Barley, and Oats, than those which he witnessed growing upon this very farm. (Applause.) This showed what could be done by a spirited farmer. At the end of four or five years after he entered on the cultivation of this farm, the tenant applied to his landlord to erect suitable buildings upon it. Sir W. Welby observed that the rental was so small, that he could not be expected to incur an outlay of that description. This farmer, however, not having the necessary confidence in a lease of 14 years to induce him to erect the necessary buildings, made an offer, that if his landlord would extend it from 14 to 21 years, he would build himself a complete range of buildings. This was agreed upon, and a better and more perfect set of buildings could not be seen than he had erected. Now, the tenant would no doubt be amply repaid for his outlay; the landlord, although he would have to wait so many years before he took any advantage from the improvement, would ultimately find his farm trebled or quadrupled in value.—*Chester Chronicle.*

The comparative Advantage of Opening Drains with the Spade and Plough.—At the second monthly meeting of the Stirling Agricultural Improvement Club, Mr. Alexander, farmer, Taylorton, read a paper on the above subject, and after a good deal of useful and interesting discussion it was unanimously resolved, "That in general cases the plough is preferable to the spade for opening drains, both as regards expedition and economy." Mr. Alexander stated that with the drain-plough he could drain 40 acres in the almost incredibly short space of four days, and that too with such exactness, that manual labour is scarcely necessary, save for the purpose of placing the tiles in the drains. He stated that the reduced rates at which drains can be opened with the plough, compared with those done with the spade, might be estimated as follows:—An ordinary day's work of both ploughs going at the same time can accomplish 10 Scotch acres; and the

TO THE NOBILITY, GENTRY, NURSERYMEN and GARDENERS.—Important SALE of Hardwick Lodge Stock, near the Shorting Station on the Liverpool and Manchester Railway.—On Monday and Tuesday, the 15th and 16th January, 1844, will be Sold by Auction, by Mr. Thomson, at his the above Gardens, 1,851 Fine Plants, of the best Sorts that are grown for Sale, viz. Flowering Plants, 240 Specimen and 405 Small Plants, particularly calla and geranium, 178 Azalias, from one to five years' old, worthy of notice; a great variety of Roses and Greenhouse Plants, Shady Exotics, Vines, Peaches, and Dwarf Trees, for bedding; Apple, Gooseberry, Currant and other Fruit-trees, &c. &c. Also, three well-bred Milch Cows, Two Mares, Fat and Store Pigs, Sow in pig, Rick of Hay, a great variety of Farming and Gardening Implements, and a Garden Engine, nearly new. Wm. Thomson, who is giving up his residence, respectfully calls the attention of Purchasers to the above Stock, which will be open for inspection on the day of Sale.

The Farming Stock will be sold on the second day. The Sale to commence each day at eleven o'clock. Catalogues may be had at the Gardens, at the Auctioneer's, and of Mr. Wall, bookseller, Wigton.

This Day is Published, price 2s. 6d. cloth boards, lettered,

THE HAND-BOOK OF CHEMISTRY; with a complete Index of Reference. By Prof. Griffith, Esq. London: W. S. Orr & Co.; and W. & R. Chambers, Edinb.

SMOKE PREVENTED AND VENTILATION EFFECTED, BY SPONTANEOUS ACTION.

MR. JEAKES, 51, Great Russell-street, Russell-square, Sole Agent in London for the Sale of RAY'S PATENT WIND GUARD, by the use of which he guarantees to Cure all Chimneys Smoking from Wind, and also to prevent downward currents; it is admirably adapted for the Ventilation of Apartments of every description, also of Ships, Stables, Dairies, and Larders, as it ensures a constant change of air, and all its parts being fixtures, it is free from noise and not liable to derangement; it also offers no impediment to sweeping. Price for general use, 30s.; larger size, 45s.; larger sizes, especially adapted for ventilation, 60s. and upwards. To be had at 51, Great Russell street, where it may be seen in action. The attention of Architects, Builders, and the Trade in general, is especially invited.

WANTED to PURCHASE, FROM 10 to 50 ACRES of LAND, with a good MANSION, or other moderate residence containing about 12 rooms, with servants' and other offices. Full particulars, stating nature of the soil, locality, dimensions and number of rooms, aspect of house, distance from church, amount of rates, taxes, and of purchase-money, to be sent free of postage to M. O., care of Mr. Pendles, 109 Fleet-street, London. Distance from London not to exceed two hours.

TO NURSERYMEN WISHING TO RETIRE FROM BUSINESS. WANTED to Purchase or Hire, an Old Established Nursery in London or its vicinity, where a good business has been carried on.—Letters addressed to C. P. L., Gardeners' Chronicle Office, 3, Charles-street, Covent-garden, will meet with immediate attention.

Price 7s., illustrated with Wood-cuts of Birds, Cages, &c. &c.

NATURAL HISTORY OF CAGE BIRDS, their Management, Habits, Food, Diseases, Treatment, Breeding, and the Methods of Catching them. By J. M. Bechstein, M.D. London: W. S. Orr and Co.; and W. & R. Chambers, Edinburgh.

NEW FARMERS' NEWSPAPER.

The time has come when Landlords and Tenants, large Farmers and small, must devote their anxious attention to improved cultivation—when, in the words of Sir Robert Peel, "*All must learn how, in the shortest time and at the least expense, to produce the greatest quantity of food, vegetable or animal, without permanent injury to the land.*" To accomplish this, no means can be so effectual as that which brings the results of Experience and Science before every man, in a cheap form. For this purpose The AGRICULTURAL GAZETTE is to be established.

The Proprietors are aware of the difficulties of dealing with the many details of cultivation without an acquaintance with circumstances, often as varying as places. They condemn the idea of conducting farming operations upon one unvariable plan, and, while they welcome science as the best auxiliary of practice, they regard crude speculations as the most dangerous of delusions. But they also feel that in Agriculture, as in all other arts, there are general principles upon which successful farming must depend, that there are practical errors which no local circumstances can justify; in short, that there is room for improvement even in those branches which are best understood. No one man can be competent to deal with the multifarious questions affecting husbandry, and the duty of the Editor of such a Paper as The AGRICULTURAL GAZETTE is to make known the knowledge of all. It is to practical Farmers that the Proprietors trust for the means of carrying out their views, and not to the talents of any individual. While, therefore, they state that the Editor of The AGRICULTURAL GAZETTE will be a gentleman well acquainted with the best kind of Farming, in which he is actively engaged, they feel it to be of far more importance to announce the promise of assistance received from the landed and farming interest generally, especially of those whose names they are permitted to mention—

The Right Hon. the Earl of Ducie, Vice President of the Royal Agricultural Society of England
Sir Charles Lemon, Bart, M P, one of the Council of the Royal Agricultural Society of England
J. E. Leaington, Esq, M. P.
Dr Bunbury, Professor of Botany, Oxford

Mr. Shoosmith, Folkington, Sussex
&c. &c. &c.

The Function of Agriculture—its Science—Animal and Vegetable Physiology—Improvements in Implements—better modes of Husbandry—results of well-conducted experimental Farming—Reclamation of Waste—Stock—Drainage—Irrigation—Foresting—Road making—Farm Buildings—Labourers—in short, whatever affects the beneficial employment of capital in land—these, and all considerations. Reports will be given of the English, Scotch, and Irish Agricultural Societies—London Market Prices of Corn, Hay, and Cattle, and the Weekly Averages. Replies to Questions connected with the object of the Paper will also be furnished weekly.

Considering the union which exists between Horticulture and Agriculture, it has been thought advisable to make The AGRICULTURAL GAZETTE an addition to the Gardeners' Chronicle, edited by Dr. Lindley, and so extensively known; but that there may be ample room for discussion, that Paper *will be increased one-half in size without additional charge*—thus Twenty-four Columns will be occupied, as at present, by Horticulture, and Twenty-four by the General News of the Week, whilst

Twenty-four Columns will be devoted to Agriculture;

This day, therefore, January 6th, is published, price SIXPENCE, stamped to go free by post, the First Number of

THE GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE:

A Weekly Record of Rural Economy and General News.

THE HORTICULTURAL PART EDITED BY PROFESSOR LINDLEY,

The principle on which the Gardening part of this Paper has been conducted has been to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Botany, so far, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are WEEKLY CALENDARS OF GARDENING OPERATIONS, given in detail and adapted to the objects of persons in every station of life, so that the Cottager with a few rods of ground before his door, the Amateur who has only a Greenhouse, and the Manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It moreover contains reports of Horticultural Meetings and Proceedings—Notices of Novelties and Improvements—in short, everything that can tend to advance the profession, benefit the condition of the workman, or contribute to the pleasure of the employer; accompanied with Woodcuts, whenever the matter treated of requires that mode of illustration.

To this Farming, as explained above, will now be added.

Lastly, that description of domestic and political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any party, their earnest endeavours have been to make The GARDENERS' CHRONICLE a full and comprehensive *Record of Facts* only—a Newspaper in the true sense of the word—leaving the reader to form his own opinions, their object being elucidation of the laws of Nature, not of men. The reader is thus furnished, IN ADDITION TO THE PECULIAR FEATURES OF THE JOURNAL, with such information concerning the events of the day as supersedes the necessity of his providing himself with any other Weekly Paper.

The Proprietors are happy to announce that the following distinguished Botanists, Florists, and Practical Gardeners have already enriched the GARDENERS' CHRONICLE by their communications:—

The Hon and Very Rev. W. Herbert, Dean of Manchester
The Hon. and Rev. Charles Bathurst
Hon. W. Fox Strangways
Sir Oswald Mosley, Bart
Sir W. J. Hooker, Royal Gardens, Kew
Mr. Bowman, Kew
Dr Lankester, F.L.S.
Rev. J. M. Berkeley
J. Bateman, Esq, Knypersley
Mr. W. Billington, Gawsworth
Mr. Ingram, Gardener to Her Majesty
Mr. Paxton, Gardener to the Duke of Devonshire
Mr. Alexander, Gardener to the Duke of Leinster
Mr. Fairgrieve, Gardener to the Duke of Buckingham
Mr. Sinclair, Gardener to the Marquis of Lansdowne
Mr. Elliott, Gardener to the Earl of Fyrconnell

The Hon and Rev. L. Vernon Harcourt
Hon Algernon Herbert
Sir George Mackenzie, Bart,
Sir Charles Wolsey, Bart.
Dr Bevan, Llanferry
Dr Gregory, Aberdeen
Dr Ingram, President of Trinity College, Oxford
Rev J D Reade
Mr Henderson, Gardener to the Earl Fitzwilliam
Mr Frost, Gardener to Lady Grenville
Mr. Heythorn, Gardener to Lord Middleton
Mr. Halliday, late Gardener to Lord Sondes
Mr. Brown, Gardener to Lord Southampton
Mr Errington, Gardener to Sir P Egerton, Bart
Mr. Fortune, Hothouse, Dept., Hort. Garden, Chiswick
Mr. Thompson, Fruit Dept., Hort. Garden, Chiswick

G Bentham, Esq, late Secretary of the Horticultural Society
L. W Dillwyn, Esq, Sketty Hall
J D. Llewelyn, Esq., Penllergare
Mr. Bailey, Gardener to the Archbishop of York
Mr. Mackintosh, Gardener to the Duke of Buccleuch
Mr. Moffat, Gardener to the Duke of Newcastle
Mr Tillery, Gardener to the Duke of Portland

SUPERB NEW DAHLIAS, to be sent out in May, 1844.—LADY GRAY (Harrison's), beautiful rosy lilac, cupped petals, full and rising centre, shows its blooms well above the foliage, good size, much larger and fuller than Miss Abbott, and fit for any stand Gained the first prize at the York grand open show, Sept. 27th; also in the first stands of 12 at Bretton open show; also in the first stands of 6, 12, and 24, at the Bradford open show; and has been admired by all who have seen it Height, 3 to 4 feet. Plants, 12s 6d

LORD HOWDEN (Harrison's), rosy bronze, beautifull, shaded, size and shape of Le Grand Baudin; full and rising centre; shows its blooms well above the foliage. Gained the first-class prize at the Great North of England open Show, also gained the first prize in the shaded or edged class at Bradford open Show, Sept 27th, as well as the premier prize, also in the first stands of 6, 12, and 24 at the same places, and was universally admired Height, 3 to 4 feet 12s 6d

J HARRISON, in offering the above SEEDLING DAHLIAS, respectfully solicits early orders, as the stock is very limited.

York, Jan 9, 1844.

DAHLIAS

J. KEYNES, FLORIST, Salisbury.—"STANDARD OF PERFECTION," (Keynes).—The finest self coloured Dahlia in the world; gained the 1st class prizes at Stonehenge, Windsor, Kingston, Surrey Zoological Gardens, and Crown and Anchor, Stockwell, also the 1st prize specimens at Stonehenge Floricultural Society, Stockwell. "It is as round as any Dahlia in cultivation, as complete an unbroken circle as could be drawn with the compasses, and as globular in front as possible It is symmetrical to a hair, and as double as a Ranunculus. It is so remarkable as to be instantly recognised among a thousand Colour deep crimson It is the flower of the season, and must be had"—*Gardeners' Gazette*, Oct. 14 "The best grown flower we ever saw, without exception, every requisite to meet the taste of a connoisseur being complied with good colour, a honeycomb, regularity of growth and disposition in the leaves, and above all, as complete a rotundity of shape as if it had been cast in a mould."—*Salisbury Herald*, Sept 2nd, 1843. Plants in May, 1844, 10s 6d "Orange Superb," (Dodd's) first rate show flower, 10s. 6d "The specimen sent would grace any stand"—Glenny "Emma Noke," (Bowding's) bluish white, extra fine, indispensable to a first rate stand, 10s 6d Catalogues containing all the fine old varieties and new flowers for the season may be had on application —Salisbury, Jan. 10, 1844

A SUCCESSFUL METHOD OF GROWING THE LISIANTHUS RUSSELLIANUS.

JAMES CUTHILL has printed the whole account of his treatment of the above most splendid plant, which has often been exhibited at Chiswick, Regent-street, and the Royal South London Societies; his largest plant this year having 600 blossoms on it, and gained the Large Silver Medal at the Royal South London Exhibition A packet of seed, with the printed directions, will be sent at the small price of 2s 6d. Also, very healthy plants of the above, from 2s and upwards Also, CUTHILL'S celebrated Early MELON, his Early improved Black Spine CUCUMBER, at 2s 6d each packet, or 6s for the three packets —Florist, Hanmark-hill, Camberwell, London

T. & C. LOCKHART & DUNCAN, SEEDSMEN AND FLORISTS, 195, Cheapside, London, have just published their List of Seeds and Ornamental Greenhouse and Hardy Plants, which they will forward free by Post, on application. They have purchased some very superior Pink Seed of one of the first growers, which they are selling in packets at 2s 6d. and 5s each. As it rarely occurs that it is offered of such quality, and as the Stock is very limited, they respectfully request early orders. If sown in March, Pink Seed flowers the same season. Early Walcheren Broccoli Seed, 4s. per ounce, sent free by Post.

BUSHELL'S Light Seedling Dahlia "EMMA."—Ground roots of this Dahlia to be disposed of for 2l. per root, for cash. Colour, white, tipped with deep cherry, the petal form and centre good; the largest, most constant and free in flowering of any Dahlia yet propagated, and has obtained several prizes. J. B. cut 48 blooms from 14 plants, which were exhibited at one of the Metropolitan Shows, the habit of which Mr. Neville pronounced it to be placed in a stand of 12. "Star Spangled."—Colour purple maroon, fine cupped petal, and fine habit; ground roots, 2l.; pot do., 1l. 5s. J. B. warrants the above Dahlias to give satisfaction, or parcels sent the purchaser [illegible] Hyde-place, Kensington-lane, Bath, 10.

FASTOLFF RASPBERRY.
YOUELL'S TOBOLSK RHUBARB.
TWO SEEDLING PICOTEES.
FINEST CARNATIONS AND PICOTEES.
ARAUCARIA IMBRICATA.

Now ready for sending out, for particulars of which see Advertisement of the 6th inst.

YOUELL & Co, Great Yarmouth Nursery, Jan. 11, 1844

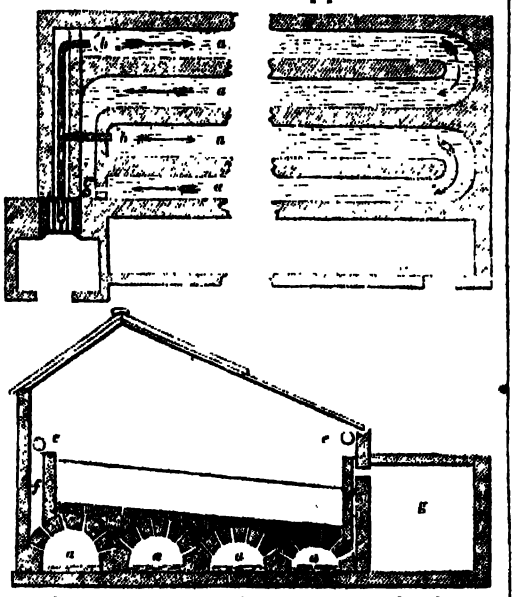
THE WALCHEREN CAULIFLOWER.

MESSRS. MARNOCK AND HANLEY beg to offer the above valuable article, warranted genuine, at 1s per ounce; sent by post if otherwise; with a Treatise on its management, so that it may be kept in succession, as for Table, throughout the year It produces beautiful, large, compact, lily-white heads, of a most delicious flavour, perfectly hardy, requiring no hand glasses; it not only produces a better quality, but a much larger quantity, on the same space of ground as the old kinds of Cauliflower. It will be quite indispensable both to large and small gardens, for no Gardener, after having once had it *true*, would wish to be without it. All kinds of Kitchen Garden, Lawn Grass, choice Imported and other Flower-seeds, warranted to grow freely, and genuine.

N B. Their Catalogues of Flower seeds, comprising everything that is new and rare, are ready, and may be had on application.

Nursery, Mossley, Jan. 4, 1844.

I mention this to show that Nature has herself hinted to us the necessity of encasing the seeds that we would preserve.



The seeds of Coniferæ, encased in their resinous integuments, are beautiful illustrations of seed-keeping, sound seeds being found in cones attached to the spray on which they grew, three or four years after the blossom that produced them had been dead. The seed-pods of the common Gorse and the Rhododendron are frequently sealed up from the foul weather of winter, and only open to scatter their seeds to the spring sunbeam; the Gorse and Rhododendron are therefore notorious examples of neglected plants, for though some may object to the Yew-tree as being an in-dweller with the grave, and perhaps not free from poison if eaten to excess by men or domestic animals, yet no such excuse can be urged against the Rhododendron, still less against the Gorse, for it is by far the best cover for game of any British plant we possess, and yields a canopy of green and gold to the landscape, food and shelter to the wild-fowl, and forage for cattle; and surely the Rhododendron might stand in all its loveliness. Wherever the wild Heath grows, there, be assured, the soil is suitable, for all Ericaceæ may follow where Calluna has been, as far as soil is concerned; and as a moderate-sized bush of Rhododendron produces at least 1000 perfect seeds annually, wonder not if fair and friendly hands go forth to sow; and thus British moorlands, proverbially brown, may yet, ere an age expire, put on a rosy hue. Nature has taught Rhododendrons to open their blossoms in early summer, to ensure impregnation, and perfect seed, and again to burst their seed-pods in early spring, to secure a favourable seed-time; therefore, if they are once put in possession of our heaths and moorlands, their posterity will be provided for, and Britain's hills adorned; for they will soon propagate themselves by myriads on every moss and moor. They do so here, and at Chatsworth in situations high and bleak, hitherto considered unfavourable to American plants, thereby proving practically the working of the plan I propose—of inoculating, as it were, by patches, the mountain's brow and wide extending moor with seeds of native and exotic evergreens, and thus bringing them piecemeal into ornamental and valuable cultivation, for I am tired of seeing square miles of "the land we live in" yielding only besom-timber.

But I hasten to the main subject, namely, the saving, preserving, and distributing of seeds with some fixed system, and according to some general plan. In the saving of seeds, I would not have gardeners to be seedsmen; yet, to a certain limited extent, is this branch forced upon us, meet it how we may. A drying-room, hot room, or something very nearly resembling a slow Corn-kiln, is essentially necessary in every garden, not only for seeds, but also for all other articles requiring drought, or liable to injury from damp, such as the nets and bunting for wall-trees, and the like; garden-mats, glazed lights, in wet weather, or when washed previous to painting; and last, though not the least necessary, the proper drying of pot-herbs—a process seldom, if ever, properly done. To prove this, it is only necessary to examine English-dried Basil, Mint, Marjoram, or the like, in bundles, leaves, and stems, or perhaps with the leaves wanting, exhibiting only a bundle of dry or mouldy stalks, dusty or damp, as the apartment chanced to be where they were stowed. Compare these, I pray you, with Chinese dried herbs! And be it known, that English herbs will dry as neatly as Chinese tea in a hot room, such as is used here and in many other places for the seasoning of green timber. Camomile flowers and the leaves of pot-herbs may in this manner be dried of a fine green colour in 48 hours; and, if canistered immediately, will keep fresh and fragrant for years. The sun is highly injurious to the drying of herbs, as it bleaches them; and as for using canisters to keep herb-leaves in, I will produce precedents by thousands, for all wise matrons must agree that canisters must be had to preserve the flavour of fine tea, and so of other leaves and flowers; in short the saving of seeds in such a manner as shall preserve in the highest degree their vital energies, requires, in our humid clime, the aid of artificial drought, and when they are dried and dressed bright and clean they must be housed in something impermeable to moisture, in a word they must be kiln-dried to ripen them off, and canistered to keep them. Scarcely any article that we possess, unless it be as obdurate as the nether-millstone, can for any length of time remain unchanged in its nature and consistency, if exposed to the jarring elements that agitate our ever-varying atmosphere: hence the imperative necessity of having seeds, and indeed everything else, isolated from the air itself, as well as the other elements, if we wish to preserve them *in statu quo*, and I have not the least doubt that if seeds were soldered air-tight in cases, after being perfectly ripe and hard dry, and excluded from the ordinary changes on the earth's surface, by being entombed deep in its bowels, they would rise and resume the place and the line of their ancestors if carefully sowed in season time, though they may have reposed a century under ground; for one grand cause of seeds not keeping is their imperfections and encumbrances. Take a powerful microscope and examine seeds six months after harvest, and you will find their coatings clammy from original or occasional damp, and eggs of devouring insects sticking to their husk, ready to begin as soon as it is warm enough to devour the store of the seed on which they have fixed their dwelling.—*A. Forsyth, Alton Towers.*

(*To be continued.*)

TANK HEATING.

The subjoined is a plan of a Pine-pit recently erected at Trentham, in which the tank system of bottom-heating and that of hot-water pipes for top-heat are combined; and for keeping a sufficient and steady heat, with a small consumption of fuel, nothing can be more satisfactory. The pit is 77 feet long, and 12 feet wide inside, and is heated by what is called a saddle-boiler. Under the bed are four tanks, *a a a a*, into which the water is delivered from the boiler, by a four-inch pipe at *b b*, and after pursuing the course indicated by the arrows is again received by another pipe, the end of which is shown at *c*. The advantage of two deliveries is that the water, not having so far to go, does not get so cold before it is returned to the boiler, and the heat is more regular in all parts of the house. The depth of water in the tanks is about 3 inches. The tanks are made of brickwork, coated with Roman cement. They are arched over with brickwork also, which we find cheaper than covering them with slates, and by leaving interstices between the bricks of which the arch is composed, the steam is allowed to escape, and penetrating the stratum of rubble above, to keep the tan in a proper state of moisture. The same boiler also supplies a range of four-inch pipe, which goes round the pit, as shown at *e* in the section. There are cavities in the wall, to permit the steam from below to pass to the top of the pit. The aperture to these can be closed at pleasure, thus insuring a perfect command over the moisture of the atmosphere. *g* is a chamber which formerly contained a flue belonging to the house that occupied the place of the one I am now describing. This chamber has been left with the view of its being useful for filling with hot dung, either for the purpose of assisting to maintain the heat of the house, or for destroying insects, thus anticipating Mr. Beaton's remarks of the week before last. The tanks and pipes cannot both be

worked at the same time, but they are fitted with stop-cocks, so that either can be worked at pleasure; and a few hours in the middle of the day, when the pipes are not wanted, is found amply sufficient to keep up the bottom-heat, as the mass of material, when once heated, retains its heat for a considerable time. I am keeping a register of the heat indicated by the thermometer out-of-doors, in the pit, and in the bed, taken every morning at daybreak—and of the quantity of coals consumed each day; and when the weather is sufficiently severe to test the efficiency of the apparatus, I will send it, if you think it will be interesting to your readers.—*G. Fleming, Trentham.*

THE ACCUMULATIVE SYSTEM OF CULTIVATION.—No. I.

At page 756 of 1843 an instance is given of the benefit of a proper mechanical texture of soil in the cultivation of Schizanthus retusus, and evidence was produced to show that the proportions of material to be employed in potting are, to a great extent, regulated by its property of maintaining a uniform circulation of moisture during the whole growth of a plant, all other conditions being equal. In the same paper mention is also made of the success attending an application of manure (as a substitute for leaf-mould) in a partial state of decomposition, to such plants as are capable of deriving nourishment from nutritive material in a gross form; and the following instance is cited of high culture being attained by a treatment, which, at that period (1832), was deemed impracticable.

Having two store pots of seedling Balsams, which had remained for some time exposed upon the front platform of a greenhouse, and the season (the end of June) being too advanced to obtain seed from them under ordinary management, it occurred to the writer, that having dispensed with the process of shifting in the growth of Schizanthus, the same operation might also be avoided in the present case. To obtain healthy plants for the experiment, they were pricked off singly in 60 sized pots, and placed on the elevated front of a small greenhouse, where, with repeated syringing, and as high a temperature from sun-heat as the situation would admit, a vigorous circulation of sap was obtained. The following compost was used:—finely-pulverised vegetable mould, having the appearance of coarse black garden soil—to which was added an equal portion of half-decomposed, dry, friable manure in flakes, the latter *only* being passed, as far as it could be reduced, through a sieve of little more than two-eighths of an inch in the wire. 12 sized pots were prepared with a bottom-drainage of one large slightly hollow potsherd, or two large flat potsherds, laid over the cavity half way, each upon the other's edge; upon these, as sub-drainage, were added two to three inches of large coarse flakes of similar material (dried by exposure to the air) closely pressed. The plants were potted firmly in this well-incorporated material. An experienced gardener observing the process of potting, remarked that the water would "rue that," meaning that the soil would prove incapable of sustaining the plants against a high temperature, and the variations of atmosphere to which they might be subject.

They were thus placed upon a tile platform and stage of a greenhouse, admitting a tolerable elevation and full exposure to light. There being no front lights, the position was well adapted for close treatment. In this situation they were subjected to as hot and humid an atmosphere as the weather would permit. Great attention was paid to giving air in the fore part of the day, for two, three, or four hours; and equal care was observed throughout the whole period of growth in maintaining a desirable temperature, by closing the house immediately on the indication of a change in the external atmosphere, as the only means of securing the highest possible degree of heat under the most unfavourable influences; and, on all occasions, when the intensity of sunlight would allow it, the house was closed (during the first and intermediate stages of growth), with a temperature varying from 70° to 90°, with requisite waterings and syringings over the whole house. By these means, a uniform and accumulated growth was obtained, to the surprise of those who anticipated opposite results. The emission of roots upon the stems, the uniform bloom, and the exuberant foliage, afforded ample proof that larger proportions of soil might have been applied with equal success. Gardeners inquired how many shifts these plants had received, and when their first growth was made; and when they were told that the position in which the plants then stood was the only one from the first shift, those cultivators could not understand the principles on which the experiment was founded, nor admit the progressive action and power of decomposed vegetable matter, when applied in a modified state, and acted upon by an intense atmospheric and solar agency. In this instance, they could not perceive that, in obtaining a simultaneous and uninterrupted growth, the means employed were equal to the effect; and that, in transferring the plants in a young and excitable state to large masses of soil, that the materials "were of a texture and quality adapted to their growth, and so mechanically arranged as to enable their tender organs to assimilate their food without being exposed to excess of moisture."* In fact, this first attempt to supersede the ordinary operations of shifting by the higher and more powerful agencies of Nature was misunderstood, and that important principle, that "atmospheric and solar agency should be so modified as to balance the power of absorption to which plants are exposed,"† and *vice versâ*, was entirely overlooked. By using portions of soil in a partially dried state, it was rendered applicable to the different stages of growth: 1st, mechanically, by its greater porosity; 2dly, nutritiously, by the gradual decomposition of organic remains in proportion to the power of absorption required for perfect growth. The foregoing instance of cultivation involves the following principles:—

1st.—For the attainment of perfect growth in plants, "it is indispensable that the supply of fluid by the roots should be continued and uninterrupted."‡

2d.—The accumulative vigour of all plants is exactly in proportion to the progressive agency of the cause to which they are first subjected.—*W. Wood.*

BEES.—No. II.

(*Continued from page 5.*)

Almost all the hives that are used about London are wider at the top than at the bottom, in order to prevent the combs from falling down; but if they were an inch or two wider at the bottom than the top or crown, the Bees would gather more honey, the process of taking out the combs would be facilitated, and the hives would not become awry so often. In the centre of the crown of each hive there ought to be a hole six inches in diameter, covered with a movable lid. To this lid a bit of comb (that working Bees are bred in) ought to be sealed, or sealed to a tally, and then pinned to the lid, to induce the Bees to make the combs run from front to back. Four or five sticks or stakes must cross from side to side of the hive, to which the Bees fasten the combs. Where sticks are thus used the Bees have passage-holes or by-ways in every comb at every stick. These by-ways are not in combs when sticks are not used. The door of the hive should be five inches wide, and nearly one inch high. The boards on which hives are placed should not be fastened to single pedestals, but be movable with the hives. That part of the board which projects in front, which the Bees arise off and alight on, ought to be eight inches broad and the same long; for if the Bees are gathering honey fast, coming home heavily loaded, they often miss the alighting-board, if it is small, and do not rise for a considerable space of time. "When a pheasant rises to fly," says Rennie, "it may be observed, first to fill its body with air by taking several deep inspirations, at the same time often rising on tip-toe, hopping a short space, and puffing out and balancing its body to feel whether it be light enough to rise." Though a pigeon does not thus hop previous to taking flight, yet it, like the pheasant, cannot go off at full speed without taking an inspiration or two. Bees, like the pheasant, generally run a short space before they

* "Farmer's Magazine," June. Page 710.
† Chronicles, p. 756.
‡ Hadley's "Principles of Horticulture," 4to.

the; but when the alighting-board is small, the Bees stand, like the pigeon, and take two or three inspirations, and in doing so obstruct the passage. The distance at which hives are placed from the ground, in most cases, is too great; for Bees sometimes miss even large boards, and experience a useful shock when they reach the ground. Hives, then, ought to be placed within six inches of the ground, with an elastic turf under the alighting-board. That Bees are more healthy at a distance from the ground is but an idle dream of philosophers. Each hive ought to be placed on three posts or stones. That rain may run off the alighting-board let the front post be a little lower than the two others.

Though Bees, when placed in a shaded corner, thrive pretty well, yet they thrive better where the sun shines on the apiary the greater part of the day; for Bees, as every good observer must know, fly faster, and are able to carry heavier burdens in sunshiny than in dull and cloudy weather. Hence, where the hives are much shaded, the Bees are apt to come to the ground before they reach them. At any rate, the Apiary should not be so closely encircled by trees as to cause the Bees to rise off the resting-board at an angle of more than 20 degrees. It may be well to remark that the excrement of Bees stains linen, and on account of this a Bee-yard ought not to be in the immediate vicinity of a drying-ground.

The Swarming of Bees.—Let us here see what takes place when Bees swarm. It must be borne in mind that a first swarm does, and a second does not leave the hive from want of room. Sometimes (generally about three days), before a first swarm is thrown, the Bees set one or more eggs in royal cells. It is not correct to say that "the swarm is led off by the queen," for she does not know whither it goes, though she follows, or rather goes with, it. About two-thirds of the Bees and the old queen form the first swarm. Though eggs are set often more and sometimes less than three days before the swarm quits the hive, yet let us suppose that in the royal cells were deposited eggs on the third day previous to swarming, and on the eleventh day after the queen's will be matured. The one that is matured first may be heard calling "off, off," in her cell. Her calling or piping being unanswered, she marches out of her cradle, and commences to call, as "peep, peep," or rather "paar, paar." Another queen is matured, and calls "off, off," which sounds seem to astonish the hatched queen, now monarch of the hive. She runs up and down the hive, crying "paar, paar;" that is, in our language, "Here am I—Where are you? death or victory." Perhaps one or more queens are matured, which call "off, off," in their cells. Having thus called for three nights a second swarm issues; that is to say, nearly the half of the Bees with the hatched queen leave the hive. While the swarm is in the act of leaving the hive, one of the queens bursts the lid of her cell, goes to the outside, runs and flies about the door for the space of a few moments, and then goes into the hive, fully expecting to be "crowned queen over all." If two should have left their cells one is put to death; but if the calling is continued a third swarm will issue on the second or third day after the second swarm issued forth. It is worthy of remark, that two queens go sometimes with the second swarm, but one of course is destroyed. If one queen only is going with the swarm, and sees or is seen by the other queen running about the mouth of the hive, a fatal contest takes place. When the queen of the colony, or swarm, or cast, is killed all the Bees return. If the following day be fine, the queens of both stock and colony come out, generally about 1 o'clock, to be fecundified. The Drones seem to be quite well aware that the young queens are about to appear, for a great part of them fly in front of the hives, "throwing their eyes around," and keeping as watchful as possible. When the queens come out they are pursued by all the Drones that see them, caught in the air, and brought to the ground, where, I believe, a union takes place. Sometimes the queens do not return; whether they fall in water, lose their way home, or mistake the hives, I am unable to say. As soon as the Bees are aware that their queens are duly impregnated, they begin to destroy the Drones. I learn from the "Honey Bee" that Bevan, Huber, Butler, and Reaumur believe, or have believed, "that the destruction of the Drones is effected by the stings of the workers." This is not the case, for the Drones are hungered to death. It is true that the Bees attempt to worry them, but they cannot do it. The Drones are banished from the combs to the boards, where, from want of food, they become so weak that they can scarcely fly. Some are unable to rise off the alighting-board, but the greater part die at a distance from home, being unable to return. On an evening, about a week after the Bees have commenced to haul and maul the Drones, you may destroy almost all the Drones in one general carnage, and thereby promote the welfare of the community. This may be done simply by lifting the hives off the boards on which the Drones are sitting, and killing them with the hand, foot, or another board.—*A. Pettigrew, Wrotham Park, Middlesex.*

(To be continued.)

Home Correspondence.

The Pseud-Acacia.—Admitting, as I readily do, the durable nature of the wood of the Pseud-Acacia, or Locust-tree, and allowing that as a gate or rail-post it may even out-last one made of sound Oak or the heart-wood of the Larch; still I think your correspondent, "A. P., Cheam," estimates its value at much too high a rate, and is giving advice to inexperienced planters, which, if generally followed, they would have reason afterwards deeply to regret; as many of those have had occasion to do who some years ago gave implicit credence to Mr. Cobbett's praises and recommendations of this same tree. As regards the growth of the Locust, which "A. P." describes as being very rapid, I would observe that this precocious growth is restricted to the first 16 or 18 years of its existence, and that afterwards its advance is at a very slow rate; indeed, so much so, that I would venture to predict that the Oaks planted by "A. P." at the same time as his Acacias, though only, as he says, half the size of the latter when twenty years old, will, by the expiration of a like period, be greatly ahead of and nearly double the size of his favourite Locusts, provided his Oaks are fairly dealt with and proper attention be given to their management in regard to thinning, &c. Again, the Acacia, even when full grown, or say when 50 or 60 years old, rarely reaches dimensions to fit it for general building purposes or where a scantling of tolerable size is required. In North America, its native country, in the rich alluvial soils to which it is usually restricted, its average diameter when at maturity seldom exceeds a foot. In this country and climate, even under the most favourable circumstances, it can scarcely be expected that its growth should exceed that of the tree in its native habitats. Besides, though "A. P." would insinuate the contrary, it will only flourish in deep rich soil; and in addition to a rich soil requires from the succulent and spreading nature of its roots, an abundance of room. If inserted in mixed plantations, in spite of its rapid growth for the first few years, it soon gets overtopped, hampered, and destroyed by its neighbours; and this happens before it acquires a size sufficient to make a remunerative return. As an intermediate occupant, therefore, it cannot enter into competition with the Larch, which grows even quicker, requires much less room, with the further advantages of a long and straight stem, and which in point of durability, under similar circumstances, is but little inferior to the Locust itself. Upon clays, cold, wet, and tilly soils, it never reaches a useful size, but in a few years becomes stunted and decays at heart. The brittle nature of its branches is also (though "A. P." seems unwilling to allow it) another great disadvantage under which it labours, as it is almost sure to be much torn and injured by the winds, except in situations well sheltered from their effects: this is against its being planted extensively, even as an ornamental tree, to which, both as regards its elegant foliage and perfumed flowers, it undoubtedly has superior claims. The liking that hares and rabbits have to the bark and young shoots of the Acacia, is also, I may add, another objection to its extensive cultivation; as where they abound it is impossible to save the plants except by some artificial protection, which, under such circumstances, would become a serious inconvenience. The tree-nails adverted to by "A. P.," I may remark, are not ship timbers, but the wooden pins with which the planks are fastened to the frame of the vessel. Those made of the Locust are found to be of first-rate quality, and are imported into England and other parts of Europe in great quantities, and at a moderate rate, from North America.—*P. J. Selby.*

Nuts.—Mr. Borrow, in his "Bible in Spain," mentions a small town near this coast entirely devoted to the cultivation, for exportation, of the Filbert. Are Filberts ever imported from Spain, or is it a mistake of Mr. Borrow's? and is it the large Spanish Nut which is grown in that country, and which is so largely imported into England?—*Totty.* [We believe that there are only two sorts of Nuts imported from Spain; a soft or Spanish Hazel from the neighbourhood of Gijon, and the Barcelona from that of Tarragona. It is probably the latter that Mr. Borrow alludes to.]

Pine Apples.—Mr. Beaton's objections to the plan of planting out Pines, on account of their fruit ripening all at one time, may, I imagine, be easily surmounted. Most gardeners agree that larger and more robust plants can be obtained in a much less time when they are planted out than when they are under pot culture. The plants also are in a more favourable position for assimilating to themselves the food necessary for the production of large fruit. I have no doubt that all apparent obstacles in the way of planting out Pines will by and by disappear. Those who are afraid of the fruit all becoming ripe at one time would do well to lift the fruiting plants from the pit and put them into large pots; they might start them into fruit at any convenient time. Mr. Glendinning says, "by planting out Pines we can have them six feet high, but this is not what we want." If Mr. Glendinning can produce plants six feet high, and otherwise proportionately well grown, and lift them and fruit them in large pots, as above mentioned, they will no doubt mature larger fruit than if they had been subjected all through to the general routine of pot culture. After the plants have fruited they may be turned out of the pots, and planted out into the soil in the bed. Only one sucker should be encouraged, and in 12 months it will be sufficiently strong to be fruited.—*C. Ewing, Bodorgan Hall, Anglesea.*

The Amherstia nobilis.—The plant of this at Chatsworth having excited the interest of some of your correspondents, I inclose an extract from a work published in 1829, describing its situation and appearance when first noticed by an European in 1826. The soil in which I saw it grow is what, in Scotland, would be called a carse. I understood the tree to be confined to the Province of Martaban, and not to exist in any other part of the Birmese dominions. The locality is between the 16° and 17° of north latitude, and about 3° north of the limit within which the Durio and Mangosteen flourish; plants, the successful culture of which would seem, like the Vine and Olive in Europe and Northern Asia, to mark a botanical or at least an agricultural region. My friend Dr. Wallich readily found the two trees which are mentioned in the following extract, but he also discovered other specimens; all, however, within the same province.—*J. Crawfurd.* "At half-past two o'clock, the tide aiding us all the while, we reached Koquin, distant by computation twenty-five miles from Martaban. The scenery in this neighbourhood was grand and beautiful, the banks of the river high, and the country to all appearance peculiarly fertile. Close to the left bank of the river was to be seen a range of mountains, steep, bare, and craggy, rising to the apparent height of 1500 feet. Almost immediately on the right bank, and where the river makes an acute angle, a number of detached conical hills rose almost perpendicularly from the plain; all these last are of a grey compact limestone. We visited the largest, which contains a spacious cave dedicated to the worship of Gautama, and which, besides having its roof rudely but curiously carved, contains several hundred images of that deity; a good number of them of pure white marble from the quarries of Ava. Around the hill is a garden belonging to a neighbouring monastery. The only plant in it which struck us as remarkable, was a tree about twenty feet high, abounding in long and pendulous panicles of rich Geranium-coloured blossoms, and long and elegant lance-shaped leaves; it is of the class and order Diadelphia Decandria, and too beautiful an object to be passed unobserved even by the uninitiated in botany. Handfuls of the flowers as offerings in the cave before the images of Gautama." *

Standard Currant-trees.—As a matter of fancy, I have for some years grown Currants as standards; and observing the constant crop that clusters round the head, and the little room they require, I potted about this time last year several three-year-old trees, and placed them on the back stage of a greenhouse; they bloomed and set their fruit well, and ripened about five or six weeks earlier than the out-door fruit. They were trained with small heads, and with the ripe fruit were remarkably showy. They are very easy to manage. The cuttings should not be shortened back, but disbudded to the top bud, repeating the disbudding till it reaches the required height. A plant three years from the cutting yielded in my greenhouse about three pints of fruit.—*M.*

Ward's Cases.—In your observations on Ward's Cases in a late *Chronicle* you mentioned that one objection to them is the dimness arising from the condensation of the moisture on the inside of the glass. This reminds me of a fact which I once met with in a scientific periodical, where it was stated by a correspondent that, having a window in which a single pane was fixed in a metal frame, the rest of the sash being of wood, he observed in winter, that while all the panes fixed in the wooden sash were frosted, that one surrounded by the metal frame remained clear from dimness. The only satisfactory explanation given referred it to the different conducting powers of the wood, glass, and metal; the latter being a better conductor of heat than the glass, because the channel of transmission, in equalising the temperature outside and inside the window, thus received the deposition of the redundant moisture in preference to the glass which it surrounded; and, in like manner, the glass being a better conductor than the wood, received the deposition of moisture in preference to the latter which surrounded it. The panes fixed in wood became frosted, while that one in metal remained clear and dry. If this solution be correct, it points out a method of obviating the deposit of moisture on the inside of the glass of Ward's Cases, without having occasion for a door or other opening. The instances appear to be analogous. The moisture held in suspension at a higher temperature begins to be deposited as that temperature becomes reduced. If the glass itself be the channel of communication through which the reduction of temperature takes place, the deposit will be on the glass; but if the glass be fixed in a frame of metal, bearing a proper proportion to the extent of glass, the function will be removed from the glass to the metal, and the former will remain dry and clear.—*J. H.*

The Constitutions of Plants.—The popular opinion that plants become naturalized, that is, adapt themselves to our climate, is a great error, and productive of much loss. The Dahlia, Heliotrope, Marvel of Peru, Potatoes, &c., are just as susceptible of frost now as when first introduced. When we hear of plants becoming hardy, as it is termed, it will generally be found that it is our ignorance, in not being sufficiently acquainted with their local habitat, an instance of which may be adduced. The Aucuba japonica, coming from a hot climate, was treated accordingly, by being placed in a stove, forgetting that the altitude of a country has great influence. The winter in Japan is very severe; India in general is very hot in the plains, whilst in the mountainous parts it is very cold: therefore, the Berberis, and other plants introduced from Nepal, are quite hardy. I could give several other instances, but sufficient has been given to enable us to arrive at the conclusion that plants retain their original constitutions unchanged.—*J. R.*

Cut Wood to have Wood.—I have no ordinary satisfaction in acceding to your wishes of laying before you the result of my planting in North Wales, as I am thoroughly persuaded that the mode of pruning which I have adopted has increased the bulk and improved the quality of the trees which have been subjected to annual pruning. I began planting as far back as 1804, in a most mountainous district, and a soil most ungrateful. As soon as the trees were removed from the nursery, I commenced pruning them, cutting two, three, or four branches, which I have continued annually, with a strong knife, close to the stem, beginning invariably at the top of the plant and descending, so as to leave the leader without a rival and balancing the

* "I showed the dry specimens of this plant to my friend Dr. Wallich, on his arrival at Rangoon, about four months afterwards, and he soon ascertained that it constituted a new genus. He afterwards examined it in person on the spot, transferred it to the Botanical Garden at Calcutta, and described it under the name of Amherstia nobilis, in compliment to the Countess of Amherst."—*Crawfurd's Embassy to the Court of Ava*, 1826.

tree as well as I could. My woodman, as well as his assistants, have persevered in this system at all seasons of the year, and the same tree once or oftener in the year, according to circumstances. As compared with others of the same age in similar situations they fully demonstrate the advantages of judicious pruning; for I do believe that more woods and hedge-row trees have been injured by pruning at distant and uncertain periods than by neglect: hence pruning, by superficial observers, has been unreasonably condemned as injurious to the growth of trees. I will call your attention more particularly to the plantations which I made in the year 1814. They have been pruned and thinned annually since that period, by taking off from 3 to 5 branches, as before described, and the result has been that the sap which the cut branches would have exhausted has given vigour and increased strength to the trunk, as is evident from the healthy appearances of the trees as well as their augmented size. I have planted those trees which the soil most loves—Oak, Larch, Ash, Sycamore, and Elm; and I often lament that gentlemen put into the ground plants without any discrimination of kind or size, consulting the nurseryman, whose object is to sell those plants which encumber his grounds. In a late Number you state, "In 26 years, Oaks, Larch, and Ash are to be found 20 feet high:" you should have added—"up to the first branch." Further—"Dr. Thackeray is represented to be continually trimming his trees up by removing the side-branches"—it should have been removing "all large or luxuriant" side-branches.—*W. M. Thackeray, Chester.*

Colour of Carnations affected by Compost.—It has been said that salts of iron tend to heighten the colour of flowers; Johnson's Almanack says, "increase the intensity of red flowers." In describing the Carnations at Messrs. Norman's, last season, the *Chronicle* observes, that Hafton's Patriarch is too thin, but that the colours are "intense." So I found them. My compost consisted of old mould from a vegetable garden, two parts—old horsedung one part, and a little charcoal. I had grown two pairs of this flower the year before, but one was sickly, and the other run—*i. e.*, the red was lost. However, I layered the run pair, and last season the layers bloomed clean and were fine plants. The flowers were evidently attractive, for a florist visited the garden without pausing before them; the white was remarkably clear, and the colours brilliant. Towards the close of the season, I chanced to visit a garden, the situation of which surpasses mine as much as the owner excels me in every quality that can constitute a florist. Here I saw several plants of Patriarch planted in a border of rich reddish-coloured soil (turned up about two years ago), but the white was quite flushed, the colours looked muddled and confused, and my friend said he was greatly disappointed with the flower, and should not grow it any more. The plants were much stronger than mine, which were in 12-sized pots. My compost had laid two winters, and was well blended; the rough stones were riddled out, and the charcoal added at potting. I could not succeed in impregnating Patriarch, although a thin flower. The style is long, thin, and in three divisions. The Pink called Barnet's Conqueror has a similar style. I never could get seed from it, though I had plenty of pollen from different varieties to cross it with, and took care to keep it dry. Bees do not seem to impregnate these flowers. In a garden where several hives were kept in the midst of a large stock of Carnations there was frequently no seed-flowers of Pinks, which were carefully impregnated and marked, produced seed, but no others on the same plant.—*J.*

Planting.—I think your Paper has increased in interest since you have taken up the subject of planting and pruning, and that parties entertaining different views on those subjects have placed them before the public through the medium of your Paper, so as to excite inquiry. So long as such discussions are carried on in the spirit which has at present shown itself, good may be expected to result from them. I have read the papers on the subject of planting and pruning, particularly on the 23d Dec., and I expect much good may result from the various opinions there given, and from the candour of the Editorial passages; but in one of those letters, "Quercus," I think, is advised to see what has occurred in the plantations at Marquis, near Chester. Now the distance from London to Chester being not more than ten hours' travel, I had hoped he would have availed himself of this suggestion, and ascertained by his own inspection the correctness of the statements in regard to these woods, and whether the system pursued there ought to be followed or rejected. I consider the permanent adorning of mountains and valleys with timber an object of such vast importance to the public, that no individual should continue to write for the eye of the public adverse to any system, the value of which, he has an opportunity of examining in person, until he has done so.—*Sub Arbore Felix, County Kerry.*

Excrescences on Timber.—I observe that your correspondent, W. Billington, (p. 909,) calls the attention of the readers of the *Gardeners' Chronicle* to some Oak trees in Pockington Park, near Oswestry, which he says are infested with excrescences of great thickness, and he then goes on to say that it appears that the timber in all such trees is shaky and of little value, and that it is carried at these excrescences by the young shoots apparently growing on dead or decaying timber; and he ends by inquiring into the cause of this. Having paid some attention to these excrescences for some years, I will endeavour to reply to his observations as they arise: first, as to the value; so far are these trees from being worthless that they are ten times as valuable as if they were plain; these excrescences when cut into veneers being most beautifully mottled and figured; and so highly are they valued by those cabinet-makers who can work them, (they are very few,) that I have known a tree of this sort sell for 100*l.* to a Leeds upholsterer. It is true that, owing to their conformation, and the long time required for seasoning all kinds of Oak-timber, they are very difficult to manage; and after having paid attention to the subject for 20 years, I do not know that I am competent to give good advice upon it. The best plan appears to be to let the tree lay in the log at least four or five years before cutting it into planks, and these planks ought to lay for two or three years before being cut into veneers; for if cut into veneers soon after the tree is felled, the shrinking of the wood and the various contortions which its mode of growth has a tendency to give it, pucker and draw, and twist them in so many directions, that the veneer is often shaken to fragments, not because the tree was originally so, but because it has been seasoned improperly. This peculiarity, and the very great difficulty there is in laying the veneers, detract much from the value of curled Oak, but it is (or was, at least some years ago) so fashionable a wood, that a good tree was worth a large sum of money notwithstanding. All curled trees, of whatever kind of wood, are valuable for this reason, if sound, and the curl has nothing to do with unsoundness, *per se*. I have myself some furniture made of the curled Elm, which I consider even more beautiful than the curled Oak, and it does not require half so long a time to get it into season. Whatever may be the cause or cure, it has certainly nothing to do with unsoundness; as I know many trees curled all round, which are growing as vigorously as any of their neighbours, and on felling curled trees I find they have the usual quantity of sap-wood upon them, but quite as much curled as the heart. This is very evident in the Elm, where the heart-wood is a fine brown, whilst the sap is white; and so far is it from being owing to the decay of the tree, that I have trees now growing not thicker than my thumb, in which this peculiarity is very evident. It appears to me that the cause is a tendency which the tree has to throw out roots from every part of its stem; and many kinds of Apples can, for this reason, be grown from cuttings as easily as so many Willows. I think it has little to do with soil, but is a constitutional peculiarity connected with variety; as in raising Crab-stocks for grafting, nurserymen will find individual plants showing this peculiarity, whilst the generality of them, although raised from the seed of the same tree, and growing in the same soil, show no such tendency. Many kinds of English timber trees are more or less affected in this way; those showing it most frequently are the Oak, Elm, Alder, Maple, Yew, Beech, Apple, Cherry, and occasionally the Ash, but I never saw a Pear-tree so affected. The celebrated Cayabuco-wood (Amboyna wood) of the East, is a production of the same kind. Recurring again to value, it is worth while ascertaining whether the twistings and contortions which detract so much from the value and beauty of curled Oak could not be remedied by injecting the tree with some extraneous matter which would fill up the pores, and prevent shrinking. According to the plan of M. Boucherie, mentioned in the *Chronicle*, at p. 911, if this could be accomplished successfully, this curled wood would be extremely valuable, as it far exceeds any other wood in beauty, the curled Elms and Yews being probably in the first class. But this is a matter of opinion, many preferring the Oak, perhaps on account of the extravagant price at which articles of furniture of this wood sell for when well made. A person of my acquaintance contrived to get some wood from one of the old Yews, near Fountains Abbey, which are said to have sheltered the monks before the abbey was built; this tree had been blown down by a strong wind, and proved to be most beautifully curled, but from its great age was too far decayed to be valuable, otherwise than as a relic of old times. In confirmation of what is said at p. 911 about the injury of coal-tar to timber, allow me to add the following fact:—A gentleman in Yorkshire had his trees much damaged by the deer in his park, and to prevent them barking them any more, he had the stems painted with coal-tar—it is true, the deer no longer attacked them, but most of them were killed by the application.—*T. G., Chitheroe.*

Cucumbers.—In reply to "Veritas," I beg to say that the Cucumbers exhibited by me at Regent-street, on the 5th of December last, were both spined, but one was ribbed and the other was smooth. My plants, both last season and also this, were propagated from cuttings; they were taken from one plant true to its kind, and the two plants subjected to experiment were grown in the same sort of soil and received the same treatment as respects heat and moisture. If, therefore, the stimulants used did not cause the difference, to what can it be attributed? "Veritas" says, "I conclude the real cause of the difference was a sporting of the variety." I am aware that Cucumbers have a tendency to sport, but this, in this instance, certainly was not the case. Hydrangea cannot be said to sport, although it is known that three different shades of colour may be produced by cultivating one in Norwood loam, another in a good Hazel loam, and a third in black fen bog, destitute of sand, and watered with a solution of alum and saltpetre. In a similar way are Dahlias, in different localities, affected by different soils.—*James Stewart.*

Canker in Auriculas.—I am sorry that Dr. Horner should think I had not attended to his Treatise on the Auricula. I have read it many times. Two things of importance I found in it: one, the time of potting; the other, the insertion of half-decayed leaves. The latter was not quite new to me. I had often seen Auriculas potted with the decayed leaves, vegetable mould, &c. from old fences; but the florists who used this compost often had unsound plants, arising most likely from bad drainage, or drip, or other causes. My own plants were very healthy, though not luxuriant. They were potted in sandy peat with some cowdung. I have the same Auriculas now that I had nine years ago. Latterly I have made up a compost for them in the month of July or August by stacking sods and loads with layers of long dung. This soon becomes very hot; and when in the course of time it is sufficiently reduced and incorporated, I take two parts of it, one part old cowdung, and half a part sharp white sand. I have used half-decayed Auricula-leaves, rags, and Fern, gathered green and laid in a heap to ferment, and sometimes I have dropped in some Lichens from the rocks and trees, with the black mould adhering to them. Every plant seems to like Fern-leaves and rags. The cankered plants which I had this year were some that I bought in spring, ready potted. On turning them out, I found a want of drainage; in some of them merely a single crock over the hole. Then they had been placed on the ground—worms had entered, and reduced the soil to a mud-paste. I never place my Auriculas on the ground, but I have seen it done by florists of some repute; and they have told me that I starved my plants by shelving them. It is true the soil in their frames was hard-rammed or trodden. I never tried the plan of sawing out the shelves to admit air to the roots, but I once happened to have some pots that were nearly cylindrical, and deep enough to allow of 4 or 5 inches of crocks. However, the plants did not thrive in them. They will grow well enough in square boxes, not too deep. I turned out into a dry poor border an Auricula of the white-edged class about 15 months ago. In winter it was partly covered during rain and frost with a pot; when I took it up, the tap-root was 4 inches long, and quite sound. I had top-dressed this plant on one side with rich compost, and on the other with charcoal earth mixed with old manure; and the fibres on this side were much whiter and healthier-looking than on the other. But charcoal-earth used as topdressing soon becomes mossy. It has been used for many years by some florists in the West Riding for an ingredient in layering, compost, piping, &c., and I believe with advantage.—*R. F.*

Mr. Loudon.—Though I am exceedingly grateful to the writers of the two letters relative to my affairs, which appeared in the *Chronicle* of Dec. 30th, I do not think it would be just to the memory of my late husband to permit the assertion that he left his family in a destitute state, to remain unexplained. He died possessed of the copyrights of 13 works, the profits from which have been so considerable that in little more than five years they have reduced a debt of 10,000*l.* to 2,400*l.* It is true that this latter sum, which is a very large one, is still owing, and that we appear at present to have no means of paying it but by the sacrifice of the copyrights; but should the same kindly feeling be extended to us that was shown to Mr. Loudon during the fortnight before his death, the debt will soon be paid, and the copyrights will remain for the benefit of the family. The appeal addressed by Mr. Loudon to the public appeared December 1st, and between that day and December 14th, the day of his lamented death, books to the amount of upwards of 300*l.*, were most liberally purchased by a number of the nobility and gentry, whose names would have appeared in the *Gardeners' Chronicle* ere this, had it not been for the melancholy event which has taken place. At present I do not know what my friends will consider best to be done; but I can only say that if any plan can be devised by which the public patronage can be obtained so as to enable us to preserve the copyrights alluded to, I shall be most truly thankful.—*J. W. Loudon, Bayswater, Jan. 3, 1844.*

Societies.

AGRICULTURAL SOCIETY OF CALCUTTA.

At the general meeting of the Agricultural Society, 18th October, amongst other proceedings, a memorandum from the overseer of the Society's garden mentioned that about 20,000 Canes, consisting of the Otaheite, Singapore, Bourbon, and China varieties, were ready for cutting; and it was agreed that these Canes should be advertised for distribution at the same charge as that of former years, viz., one anna for each Cane. The secretary mentioned that he had submitted Mr. Scoones's sample of Tea, grown and manufactured at Chittagong, from leaves of Assam plants, to Mr. Charles Terry, and that gentleman had made the following report thereon:—"I have examined the sample of Tea you sent me, the produce of Chittagong. It is a superior Tea in flavour, also in strength, and is of the Pekoe class. Had it been well manufactured, it would command a good price in the English market." A letter from Mr. Stikeman, secretary to the East India and China Association, stated that, by the intervention of Dr. Royle, some nuts of the Cacao had been procured for the Society from the West Indies; and a letter from Capt. Marquard communicated the transfer of the greater portion of the Chocolate-trees in his garden at Chittagong to that of the Society. On the 8th Nov., in consequence of the paucity of applications for Sugar-cane, the charge was reduced to one-half.—*Indian Mail.*

COUNTRY SHOWS.

Ipswich Cucumber Society, Jan. 8.—This was the annual meeting, and on this occasion a very handsome supply of game was sent for dinner by the President, the Right Hon. Lord Rendlesham, M.P. After the usual loyal toasts, the following were some of the Horticultural:—"The health of Lord Rendlesham, P. B. Long, Esq., and the Vice Presidents," &c. &c. "Dr. Lindley, and success to the *Gardeners' Chronicle and Agricultural Gazette.*" "To the memory of the late J. C. Loudon, Esq., (whose zeal and talent as an author, on Gardening and other subjects connected with rural and domestic economy, has justly won the golden opinions of scientific men, both at home and abroad); and may the leaders of the gardening republic hereafter forth prove themselves as worthy of our esteem." "To the Benton, well known from his writings in the Columbian *Gardeners' Chronicle.*" Also "Success to all Cucumber Societies,

and may they soon make known their Show days for 1844." After a discussion on Cucumbers, the new system of cultivating Pines, the sure of scale, and Rendle's Tank system, on which the meeting could not understand how the necessary *top-heat* was produced, the evening was spent in the greatest harmony and conviviality.—*Thomas Wills, Hon. Secretary.*

Limerick Practical Horticultural Society.—On New Year's Day the report of the progress of the Society for the past year was read by G. Bevan, Esq., from which it appeared that nearly 300 prizes in the various classes of Fruit, Flowers, and Vegetables, were distributed to the gardeners who were competitors at the three exhibitions in 1843. The late treasurer, Mr. Bevan, has been obliged, by other avocations, to resign the treasurership and management of the exhibitions, which has been so successfully conducted by him during the past three years. Mr. W. Wilson has been elected in his room.

NOTICES of NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

PHASEOLUS CARACALLA. The Snail-flower. (*Stove Perennial.*) Leguminosæ. Diadelphia Decandria.—None but a Botanist would, at first sight, detect any resemblance between the flowers of this extraordinary plant and those of the common Kidney-bean. And yet they both belong to the same genus. Many curious instances exist in the vegetable kingdom, in which observers have found some real or fancied similarity to objects in the animal world: and the one before us is by no means the least noticeable. In the spiral form of the folded flowers, ere they are expanded, there is assuredly something not unlike the anatomy of the snail. And though the thing with which the flower is thus compared by no means augments its interest, from association, nothing but the figure of the snail, and not its repulsive character, is thought of while we admire this singular and really delightful production. Having been one of the first exotics cultivated in this country, it has lost much of its attraction in modern times. Indeed, it is rarely seen in collections of stove plants: we learn, however, that it has recently acquired the name of Glycine or Wistaria Harrisonii, and in that way is being put forth as a novelty. The species is a deciduous stove-twiner, native of the East Indies, bearing long racemes of large flowers, which are of a purple and yellowish hue. They have a very graceful appearance, depending from the slender branches. The plant can be cultivated with difficulty in a slightly enriched loamy soil; but it is said to be liable to the attacks of the red spider, from which it may be kept free by syringing, and by placing it in a moist atmosphere. It is a good plant for training up the rafters of a house, where its fine racemes of bloom will be shown advantageously. It is a rare and highly ornamental plant, with very fragrant flowers, and of difficult management. In many parts of the south of Europe and the north of Africa it is grown for culinary purposes; the pods, we presume, being the parts used. The Portuguese, who introduced the species from South America, named it Caracalla, in consequence of its hooded flower. It is one of that rare class of plants which combine the ornamental with the curious.—*Paxton's Magazine of Botany.*

TACSONIA PINNATISTIPULA. Mrs. Marryatt's Tacsonia, or Passion-flower. (*Greenhouse Climber.*) Passifloreæ. Monadelphia Pentandria.—This truly handsome plant is not cultivated so much as it deserves to be in the greenhouses and conservatories of this country, considering how long it has existed in our collections, and how readily it may be increased by cuttings. It is a native of Chili, and was introduced by Mrs. Marryatt, of Wimbledon House, about the year 1830. Nor do we think the trial has fairly been made in the open air, to ascertain whether it could not at least be made to flourish during the summer months, by protecting the roots in winter. The native climate of this Passion-flower is not so warm as that of our Passiflora cærulea. With us, in the Royal Botanic Gardens, it is trained to the back-wall of a cool greenhouse, where it flowers in the summer months.—*Curtis's Botanical Magazine.*

ONCIDIUM BICOLOR. Two-coloured Oncidium. (*Stove Epiphyte.*) Orchidaceæ. Gynandria Monandria.—This charming species of Oncidium, one of the rarest of its genus, was obtained by Messrs. Loddiges from the Spanish Main, and is 1243 of their catalogue. It flowered with them in September, 1842. Among other peculiarities of the species may be mentioned its very thin pseudo-bulbs and three-lobed crest of the labellum, the front lobe of which projects forward, while the laterals are at right angles to it and slightly toothed. It has, moreover, a very large lip, which although deep clear yellow on the upper side, is almost white underneath, as also happens in some of the Chive-leaved species. Its nearest affinity is with O. bifolium.—*Botanical Register.*

BOSSIÆA PAUCIFOLIA. Few-leaved Bossiæa. (*Greenhouse Shrub.*) Leguminosæ. Diadelphia Decandria.—This New Holland bush, which has been raised several times from Swan River seeds, is one of those plants whose appearance depends chiefly upon the way in which it is managed. Under ordinary circumstances it is a straggling, naked, inelegant species; but when kept dwarf, and in very good health, it forms a pretty compact bush, gaily sprinkled with yellow and crimson blossoms. It was originally raised from seeds by Robert Mangles, Esq., of Sunning Hill; and in July, 1841, it was named and defined in this work by Mr. Bentham. Afterwards, in December, 1842, it was figured in the "Botanical Magazine" under the name of B. virgata, Sir William Hooker not being aware that it had been already published. It is a greenhouse shrub, and will best succeed if potted in rough peat mixed with a little loam and sand. When potted, the stock should never be immersed in the soil, but rather a little elevated, which will preserve the plant from damping off in winter. In summer an ample supply of water should be given, and air at all times. In winter it should be exposed as much as possible to the light, and always receive air when the weather will permit. Fire heat should never be applied, except to keep off frost. It may be propagated from seeds or cuttings.—*Botanical Register.*

GARDEN MEMORANDA.

Lee Hall, Little Woolton, near Liverpool. — The Orangery at this place contains an excellent collection of the best sorts of the genus Citrus. The greater part of the plants are growing in pits, and furnish a striking example of the superiority of this system over that of growing them in pots or boxes. The golden fruits of this genus, reposing among the lively green leaves that under good cultivation the tribe always carries, has an interesting effect at this time of the year, when there are but few flowers to enliven the Conservatory or other ornamental-plant-houses. Were it only for its beauty, to say nothing of its usefulness, this tribe merits attention. One-half of the back wall of the Orangery is covered by a plant of Peidiem Cattleyanum, bearing excellent fruit; the other half by a plant of the common Shaddock, also bearing some fine fruit. Passing into a Pine stove to the west of the Orangery, the visitor is delighted at the beautiful appearance of the Oranges, Citrons, &c., trained over the back path. A border a little more than a foot in breadth is partitioned off from the back of the bark pit, running its whole length and depth. In this border the Oranges, Citrons, &c., are planted; and in this situation the plants have the advantage of a little bottom-heat, as the partition is but the thickness of a brick set on edge. The branches are trained on a wire trellis over the back path, and bear an abundance of fine fruit every year. At one end of the arch a Shaddock bearing very large fruit is a conspicuous object. The back path of a Pine stove on the east side of the Orangery is covered with Oranges, &c., similar to that in the house already mentioned, and growing with equal luxuriance. Adjoining this stove is a house about 70 feet in length and 24 in breadth, which the gardener, Mr. Piggot, informed me is intended almost entirely for Conservatory climbers. The greater part of them will be planted out in the borders inside the house, and will doubtless have a fine effect. At present the house is principally occupied by Orange-trees, Amaryllidaceæ, and select bulbous plants of various genera. The Greenhouse contains principally a stock of young plants, which are designed to render it gay during summer. In the centre of another range of stoves is a small house devoted to the cultivation of Musa Cavendishii. The central pit is filled with earth, in which the plants are luxuriating. One of these plants is carrying a very large bunch of fruit. Mr. Oakhill, the proprietor, has paid great attention to the culture of all kinds of bulbous plants; and the many fine specimens among them bear ample evidence of good treatment. The Amaryllises at present in flower are chiefly hybrids, between vittata and Johnsonii, some of them exceeding either of their parents in beauty, and all of them very showy. For a Conservatory Amaryllidaceæ possess so many good points in their character that they cannot be too strongly recommended. The greater part of them produce large gorgeous flowers; they are easy to cultivate; may be made, when well managed, to flower at any season; and take up little room. The varieties, by hybridising, may be multiplied almost to infinity. The collection of Orchidaceæ here is but small, Mr. Oakhill having only recently commenced growing them. Numbers have lately been received from the Organ Mountains in Brazil, some of which appear new, but have not yet flowered; amongst them is a pretty little Odontoglossum in flower, which I have not seen elsewhere. A large plant of the old Phaius grandifolius, with 12 or 14 spikes of flowers, and Bletia Shepherdii, with Neottia speciosa and Rodriguezia recurva, are all finely in flower. Ardisia crenulata and Euphorbia jacquiniflora are, as is usually the case when well treated, now very showy; the latter plant occupied a small square pit in the corner of a bark bed, and is thriving well. The Pines, which occupy six of the central pits in the like number of houses, are looking very well and some of them are carrying fine fruit. There are no houses entirely devoted to Vines, they are planted in borders in front of the Pine stoves, and trained up the rafters over the Pines. —*J. W. Jones.*

Miscellaneous.

The Elæagnus reflexa, of Japan.—This plant was introduced from Belgium, into the Garden of Plants, at Paris, in 1837. It flowered for the first time in the open air in 1841, but more abundantly in October, 1842. It is a very branchy shrub, the largest plant of which is now three yards high. The leaves are alternate, and evergreen. The little bunches of flowers are solitary at the axil of the leaves, and there are three or six flowers together in a cluster, which is about half an inch long. This shrub is worthy the attention of Horticulturists, as it can endure the rigour of our winters, notwithstanding that it is always growing. In this it resembles our Alaternuses and Phyllireas; but it is certainly to be preferred on account of its elegant foliage and odoriferous flowers, which are as sweet as those of the Bohemian Olive, but less penetrating. It can be easily propagated by cuttings put under a bell-glass, and kept in a mild, damp atmosphere. Hitherto it has been grown in peat, in a shady situation. It would fruit, perhaps, in a proper soil, if that could be made.—*Rev. Hort.* [This is apparently the Elæagnus parviflora, mentioned at p. and figured in the "Botanic Register" for 1843, tab. 51.]

Poisonous Nature of Hemlock and Oleander.—A case of poisoning with Hemlock (*Conium maculatum*), occurred lately in consequence of the ignorance of a cook-maid, who had mistaken the above plant for Chervil, and as such employed it in a salad, all who partook of which became seriously ill. It may be remarked that the Hemlock would not have produced so bad an effect if it had been employed in soup, or in any preparation requiring fire-heat. The poisonous principles of the Hemlock (*conceine*) is volatile, and disappears by boiling. The cook-maid declared that she had employed this plant some days previously for soup; and she persisted in saying that it was the same as that which caused the illness when used in salad. A few years ago, a child died from having eaten one morning a quantity of Oleander flowers. The child was seized with violent colic, and whilst the cause of its indisposition was unknown, the symptoms soon assumed an alarming character, that of a burning fever, under which the child sunk at the end of two days. With reference to this last case we may mention the following, related by Professor Richard. In 1809, when the French troops were lying before Madrid, some of the soldiers went a marauding, every one bringing back such provisions as could be found. One soldier formed the unfortunate idea of cutting the branches of the Oleander for spits and skewers for the meat when roasting. This tree, it may be observed, is very common in Spain, where it attains considerable dimensions. The wood having been stripped of its bark, and brought in contact with the meat, was productive of most direful consequences, for of twelve soldiers who ate of the roast seven died, and the other five were dangerously ill. An order of the day was issued next morning, interdicting the cutting of the Oleander. This plant belongs to the Apocinaceous family, of which nearly all the plants are deleterious, and contain a white acrid juice, more or less thick, and produce eruptions if applied to the skin. M. Pépin states that during the wars of Italy, an instance of poisoning occurred in consequence of soldiers employing branches of the common Laurel (*Cerasus Laurocerasus*) for roasting their meat.—*Revue Horticole.*||

Experiments on various Flowering Plants, with Guano and Nitrate of Soda. By J. E. TEICHMACHER.—Small parcels of the new manure Guano having been very generally circulated in this vicinity, it is right to put those in possession of it on their guard against using it too freely, many plants in England and some here having been killed for want of proper care in the application of it. Guano is an extremely powerful and warm manure, and if applied in large quantities, or in lumps, destroys the roots. For Pelargoniums, Roses, and all hardy, strong-growing plants, one teaspoonful to a quart of earth, or about 1 part in 100, is sufficient; it should be pulverised and well mixed with the earth in which a plant is to be repotted. When it is not convenient to repot, the earth may be gently stirred on the surface of the pot one or two inches deep, and the Guano pulverised, then mixed in; the plants should be kept well watered. Besides Pelargoniums and Roses, I have tried it on the Myrtaceous family, on Erica, Fuchsias, and Camellias; its effects on these are equally surprising. I have been also trying experiments on various plants with nitrate of soda; in every case I placed two plants, of the same species and of nearly the same size, close together; one of them was watered three times a week with a very weak solution of this salt, the other was under the usual management. The effect of the nitrate of soda has now become very evident, the plants watered with it are larger and earlier in bloom than the others; it appears, however, to me, probable that these effects will be rather evanescent, and the plants will always require this stimulant. I observe in the English publications, that this constant necessity for the stimulant is urged against all these new manures, but surely there is no strength in this argument. All manures become exhausted, and the farmer has always to apply the stimulant of his manure-heap to make his land bear. From some experiments I have made, I think that Guano will prove a manure of much greater permanence than any that is now in use, particularly in soils deficient in phosphate of lime.—*Hovey's Magazine of Horticulture.*

Adulteration of Sugar.—A supply of crushed sugar arrived in Perth, a few days ago, with all the appearance of adulteration. Samples have been submitted to chemical tests, but hitherto, we understand, without detecting the peculiar ingredients of admixture. To appearance it is some mucilage or starchy substance, giving the sugar a peculiar clammy moisture, as well as smell. Suspicions of adulteration have been entertained here for some time, not only in crushed, but in lump sugar. A large quantity of the latter having been dissolved previous to being boiled with fruit for jelly, was found to contain a large portion of glutinous or starchy matter, but the exact ingredient could not be ascertained.—*Perth Courier.* [*We* never saw or heard of such an adulteration of loaf or crushed sugar, and rather doubt it; brown sugar is often, and to a great extent, adulterated with various cheap substances like that described, but we do not understand how loaf-sugar could be so adulterated.]

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

Stoves.—If the paths, stages, plants, &c., are kept clean, and the heating apparatus is in a good working condition, there will be little necessity for giving much air, at this season, to stove plants at rest and in dull weather. Formerly, currents of air were thought so indispensable to plants at all times, that increased fires were made purposely to rise the temperature higher than was necessary, in order to keep up these currents.

Conservatory.—A great step towards the proper management of stove plants in winter was made when those in flower at this season were found to do well enough in a temperature averaging 45° in the conservatory. Euphorbia jacquiniflora is the best stove plant we have for winter, and the flowers are even more brilliant in the conservatory than in the stove. Among the forced flowers the Narcissi, Hyacinths, early Tulips, with some of the different Roses, are now the most prominent; Sweetbrier is always welcome in winter, and no place should be without Mignonette in pots and boxes. Polygala chamæbuxia, a very dwarf old plant, is excellent for forcing, and will keep a long time in flower in any dark corner where little else would thrive; it requires abundance of water.

Greenhouse.—There are frequent failures from careless watering of greenhouse plants in winter, not by too much, but the contrary; the best criterion is to have all the soil in the pot of equal dampness throughout, and something between wet and dry. Keep these and all other plants free from dead leaves and insects, and neatly tied up to stakes, or trained, according to the habit of the plants.

Forcing Pits.—These are now crowded with Roses, Lilacs, both the common and Persian, Sweetbriar, Cinerarias, Hyacinths, Tulips, Narcissi, Jonquils, Anna Boleyn Pinks, Gardenias, Rondeletia speciosa, Franciscea Hopeana and latifolia, Acacia of sorts, Crotalarias, Pelargoniums, Chinese and other Azaleas, with Rhododendrons, Andromedas, &c. These may be syringed once a day, and smoked occasionally, and a temperature of from 55° to 65° should be maintained.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

The remarks of last week in this department are still applicable. As the weather is mild, the planting of shrubs and trees may be proceeded with, as may also the pruning, where pruning is necessary. This is a good time to lay new turf, or repair turf edgings.

Reserve Garden.—All the spare ground in this department, if not already dug, should be laid up into frost-ridges; and where the ground is heavy, a good dressing of leaf-mould and sand, 2 or 3 inches thick, will do much to improve it. Take advantage of frosty weather to get in a quantity of sand to plunge half-hardy plants into when hardening off for the flower garden.

Pits and Frames.—Take advantage of the first leisure hour to "take stock" of the plants for budding out in these structures; and if you have not sufficient stock of some kinds, introduce a few plants into heat to produce cuttings to propagate from.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Directions for the management of this department of Flora's kingdom have been given in various shapes in almost every work on Floriculture that has hitherto been published, so that any one attempting a similar directory may very easily be charged with plagiarism, and accused of re-issuing other Florists' opinions. The writer of the accompanying memoranda will not, however, be deterred from recording his opinions because they may happen to coincide with some other writer's previously published. They will be the result of many years' experience, added to observations made during the current year.

Auriculas require great attention just now. If healthy, they will withstand intense frost with impunity; care must be taken to remove decayed leaves, stripping them downward to avoid wounding the stem. The surface soil should be kept stirred, and the plants be allowed all the air possible; bearing in mind that drip or too much moisture at this season is their bane.

Polyanthuses must have all trusses of flowers removed as they show themselves, if good blooms are to be expected at the proper season of exhibition.

Tulips are peeping. Cover on frosty nights with mats on hoops placed across the bed. If sand is put on them it must be white or Calais sand, as I have known parties who covered with pit sand, impregnated with iron, which had a most deleterious effect on the foliage afterwards.

Carnations must have all air possible; if they are well established, and of a fine glaucous hue they require but little attention in comparison with those that have been potted late. If in frames, bricks ought to be put at each corner, raising the wood-work at least four inches from the ground, to secure good ventilation.

Ranunculus beds, which ought to have been prepared in autumn, may have a dressing of old cow manure and decayed leaves forked slightly in, preparatory to planting in February.

Examine *Pink* beds, and where the pipings have been raised by the frost or worms, they must be carefully fastened.

In bad weather labels ought to be made, handglasses mended, leaden layer pegs straightened, Carnation sticks made, &c.—*W. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—If the bottom-heat falls below 90° in the fruiting-pit, it should be revived by loosening the tan or leaves between the pots with a fork, and adding a few inches of fresh tan. If a stock of leaves have not already been collected, no time should be lost; when it is favourable weather, they should be collected into a heap and covered, so as to keep them dry. A supply of the should always be in readiness, and kept dry. By keeping a supply of everything required in readiness, and in a fit state for use, the plants receive less check at the time of shifting.

Vinery.—In the earliest house, if the principal buds are broken, and showing fruit, let the heat by night be 60°, raising it to 70° or 75° by day, and by sun-heat to 85°. Except in cases where wood is wanting, stop the shoots on which fruit is showing at one joint above the fruit. Rub off all useless shoots as they appear. Proceed gently with the Vines just breaking, taking care not to let the heat exceed 55° by night, until all the principal buds are broken, and keep the shoots always moist.

Peach-house.—From the time the blossoms begin to expand, avoid syringing till the fruit is set. During the time the trees are in bloom, maintain a steady heat of 57° by night, and admit fresh air every day if the weather will admit it. If the sun raises the thermometer as high as 75° with the sashes or ventilators open, it will assist the setting of the fruit.

Fig-house.—Now is a good time to commence forcing the Figs, as they continue bearing from the end of May till September or October; begin with a temperature of from 45° to 50° by night, with a moist atmosphere.

Strawberries.—Besides those recommended to be placed in a forcing-pit last week, it will be well to take some into a cool Vinery or Peach-house, and place them on the shelves or on the floor. They will be coming on to succeed those already in the pits when the latter are removed to swell off their crop on the shelves of the Vinery.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Figs—Should be protected, if not already done. The method most generally practicable is to unnail the trees, tie them closely together, wind a little straw among the branches, and cover neatly with mats. Pruning and nailing may be proceeded with in favourable weather, except in the case of Peaches and Apricots.

Filbert-trees.—Regulate their heads and remove suckers.

Peas and Beans.—Defend forward crops from slugs, by quick lime and coal-ashes, or send a boy to strew tender leaves of Cabbage on the ground, and to examine them every morning. Protect intended crops from mice, by sowing chopped Furze along with them. The awns or chaff of Barley are useful for the same purpose.

Endive and Chicory.—The former may be blanched, and the latter grown and blanched beautifully, in any dark place commanding a temperature of from 50 to 55°.

Potatoes.—Be getting ready some fermenting materials for forwarding the earliest crops in pits or boxes. We have had young ones for some time, obtained from old tubers, placed in alternate layers with earth, in a shed, in the end of August.

Mushroom Beds.—The principal things to be guarded against, (especially with out-door beds) are too much heat and too much wet. Where a constant supply all the year is wanted, a series of slight beds, rapidly succeeding each other, will answer the purpose better than one or two large ones. Horse droppings mixed with a good quantity of litter answer best for shelves, but when many are required it will not do to be very particular in choosing the material, provided it is capable of producing a mild heat, but we must regulate future operations according to the material. We will again advert to this subject.

Asparagus, Seakale, and Rhubarb.—See that beds producing do not get too hot after the late frost. *R. F.*

VI.—ARBORICULTURE

Old Woods.—Continue the felling of trees not required for the bark. When Oak timber is required to endure for "ages to come" it is undoubtedly best to fell it in winter with the bark on, and before the trees begin naturally to decay. Resinous trees, for durability, should be felled just before the buds and leaves expand, when the sap is in motion. Fill up vacant spaces with young plants suitable to the soil, locality, and demand. Take great care to preserve any maiden plants of proper kinds springing up naturally, and let them be properly trained.

Coppice.—Proceed with cutting the undergrowth and poles, for the uses specified last week, and guard against a vigorous after-growth. Continue to clean out and make fresh drains where required; also, clean out old water-courses, and fill up open spaces with young plants suitable to the soil, locality, and demand for the produce; keep this circumstance always in view when planting for Coppice. The Prunus padus, Bird Cherry, or Hagberry of the North of England, is an excellent Coppice-wood for all the purposes of the Hazel; I am surprised it is not cultivated in the midland and southern counties. Defer planting in wet coppice till March or April.

Young Plantations.—Continue here the directions given last week. In thinning young plantations, where they have been planted promiscuously with various kinds of trees, leave them in irregular groups, or masses, either large or small, according to the extent of the plantations, each kind by themselves, as it will be seen about this time which plants thrive best in the different parts.

Hedge-rows.—Continue to plant young trees, and take care of those that have sprung up naturally there, as directed last week. Be sure to have good stocky plants for the purpose; not drawn-up, weak ones, out of the interior of close woods and crowded nurseries, but with plenty of side-branches to balance them. Avoid planting Ash in arable land.

Nursery Work.—Go on with the work specified last week, and in procuring seeds for sowing, and plants for planting out in rows for future use; get some of the Hagberry or Bird Cherry, if you can; it is easily raised by cuttings or layers, as well as seeds; it likes moist ground. It is not only valuable as a Coppice-wood, but very ornamental in hedges or woods. I am strongly of opinion it is a very valuable hard wood when it arrives at a good size, but my experience is not sufficient to speak with confidence to its quality as timber.—*W. B.*

VII.—COTTAGERS' GARDENS.

At this season, when there is little to be done in the way of cropping, everything around the cottage should be made clean and neat; all vegetable refuse may be collected into a heap, to rot for manure—nothing of this kind should be lost. Vacant ground, if any, may be turned up rough, to be fully exposed to the action of the weather; this is especially necessary for strong soils, in order that the frost may separate their parts and render them more friable. When manure is applied, a little at a time, and as often as an opportunity and the nature of the crops will allow, is better than when the ground is over-loaded with dung.

Vegetables.—If a sowing of Peas and Beans have not yet been made, no time should be lost in getting them in while the weather continues favourable.

Fruit.—Continue to prune any fruit-trees if not done last week, taking care, however, to keep the spurs short and close, otherwise they soon become long and give the trees an unsightly appearance.

Flowers.—Remove everything unsightly from the flower-plot. Nothing looks worse than to see decayed stems of plants standing at this season, as is too often the case. Bulbs, if any, that have made their appearance above ground, should be protected in the event of frosty weather, but not unless, as this has a tendency to make them weak and tender.—*Mc. H.*

State of the Weather near London for the week ending Jan. 11, 1844, as observed at the Horticultural Garden, Chiswick.

The highest temperature during the above period occurred on the 18th, 1834—thermometer 59°; and the lowest on the night of the 19th and morning of the 20th, 1838—thermometer 4½ below zero.

Notices to Correspondents.

MR. PAXTON'S COTTAGER'S CALENDAR.—At the earnest solicitation of many of our Subscribers, we have determined on again reprinting Mr. Paxton's "Cottager's Calendar," in the form of a small volume, for general distribution, price 3*d.* each copy. It may be ordered of all booksellers. Gentlemen wishing to *distribute copies* among their cottage tenantry, may have them *delivered in any part of London*, by remitting a post-office order to this office, at the rate of 5*s.* for every 25 copies.

COMMUNICATIONS from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them:—*J. Paxton, J. Snow, Herts, J. Wighton, C. G. Thompson, A Practical Man, P. Mackenzie, Totty.*

BOOKS.—*A. Z.*—You will not get any good periodical on Gardening generally, with coloured plates, which costs less than 2*s.* a month.—*A. Subscriber.*—There is no book on the diseases of plants. We shall try to supply the deficiency.

CALCEOLARIAS.—*J. B.*—When you mention clay in the centre of your pots, and that you have kept your plants dry, you fully explain the history of your misfortunes. There is a good paper on the management of Calceolarias at p. 341, vol. 1841.

CAMELLIAS.—*E. B. W.*—Both the spotting and yellowness of your leaves, which nevertheless are very healthy, are owing to the action of strong light collected in a focus by some concave panes of glass in your roof. The whiteness found in leaves otherwise is usually owing to a cold wet bottom.

CACTUS SPECIOSISSIMUS.—*A Subscriber.*—The cause of your Cactus becoming discoloured and cankered, is, no doubt, owing to its being kept too cold and damp, as the plant has been kept in a greenhouse, where the temperature varies from 40° to 50°, and where plenty of air has been admitted; the dampness very probably arises from the atmosphere, the plants being otherwise kept almost dry. The disease is not at all infectious; the healthy plants likewise becoming infected, no doubt, is the result of the same cause. The fact of the disease attacking the most healthy branches is perfectly consistent, as they, being more succulent, would be readiest to suffer from dampness. The diseased parts may be cut off, and the plant should be placed in a warmer situation. To make the plant bloom freely, continue to withhold water until March or April, when the blossom-buds will begin to appear; water may then be more liberally supplied.‡

CARROTS.—*Leeds.*—The White Carrot is not, in our opinion, so good for the table as the Red varieties.

CHRYSANTHEMUMS.—*A Waterford Subscriber.*—The kinds to select to save seed from are the semi-double varieties; they should be kept in a dry place, and have their heads preserved from damp. So much having been advanced in our columns respecting root-pruning in former volumes, we are unwilling at present to resume the subject.‡

CUCUMBERS, &c.—*J. Hall.*—One of the best Melons is the Beechwood. There are now so many varieties of Cucumber, that it is difficult to say which is the best; possibly Weedon's "Black Spine" will suit you. The soil best adapted for growing them in is a very rich strong loam. A frame, covered with calico prepared with Whitney's composition, will answer very well for growing Cucumbers in during the summer time, but it is not possible to force them in such a frame.‡

FRUIT-TREES.—*A Subscriber.*—Your Apricot-trees, that have been planted 10 or 11 years, will be most likely brought into a bearing state by taking them up, trenching the border, mixing the soil with chopped turf (if such can be obtained), and then replanting the trees, spreading the roots near the surface. A top-dressing of lime will tend to prevent mildew, often the most formidable of all evils as regards the Apricot-tree.‡

FUCHSIA-SEED.—*A Reader, M.*—You may sow your Fuchsia-seed about the latter end of February or beginning of March; if it is sown sooner without the aid of a greenhouse, the young plants would be likely to damp off. The seed may be sown in pans filled with light sandy loam; if you have a gentle hotbed they might be placed on it; but they should be removed as soon as the seeds begin to germinate, as Fuchsias are rather impatient of artificial heat.‡

GREENHOUSE PLANTS.—*G. F.*—Probably your plants are ill-drained; examine the pots and see to the crocks. Probably the house is too damp, and wants ventilation. Kill the green-fly with gas-water as directed at p. 449 if they are hard-wooded; or with tobacco-smoke if soft plants. The smoke of turf will do no harm, but it is better excluded from your greenhouses.

HEATING.—*Leeds.*—As your tenancy is short, it is not worth while to build brick pits; and, as a make-shift, you had better be satisfied with a common hot-bed.—*M. O. B.*—We see nothing to object to in your plan; but it is unnecessary to provide any means of giving a hotbed dry heat, because it is never required, unless you are going to grow bulbs of some sort in it.—*A Friend.*—We like your plan, and will have it engraved. It is always difficult to find a good boiler for a very little work. Perhaps a very nice boiler, by Burbidge and Healy, with an evaporating top, would be the best and cheapest under your circumstances. We should be tempted to try it.

INSECTS.—*G. S. T.*—The Coccus Vitis only affects the stem and branches of the Vine, and it may be eradicated by stripping off and burning the old bark in the winter, and washing the denuded parts with soap and water, or perhaps lime and water; but if the tortoise-bug give an unsightly appearance to the leaves and fruit, we conclude it must be a species with which we are unacquainted, and will thank our Correspondent to transmit some, per post, in a pill-box, together with an injured leaf or two, directed to Mr. Curtis. *R.*

LARCHES.—*J.* wishes to plant a small belt on a light poor soil on a chalky bottom—would Mr. Prideaux Selby recommend Larch or Beech as most likely to grow up quickly and repay itself?

LEMONS.—*G. F.*—Take your Lemons out of their tubs, shake off all the old soil, and repot them in coarse turfy loam, mixed with one-third charcoal, steeped in guano-water, or strong liquid manure of some sort. Give them plenty of pot-room, cut them in, start them in a good bottom-heat if you can, and they will soon lose their yellow looks. Manure cannot do them any good till they begin to grow.

MUSHROOMS.—Vide Calendar, Jan. 20 of the present year.

NAMES OF FRUIT.—*R. P.*—Your Pear is the Beurré Rance. ‖

NAMES OF PLANTS.—*T. G., Clitheroe.*—The seeds appear to belong to some Asclepiadaceous plant.—*J. L. S.*—As your specimen is not in flower, it is hard to say whether it is Aristea pusilla or not; it probably is.—*Δ.*—Flemingia strobilifera.—*J. M. F.*—Scolopendrium officinarum; not Kennedya at all; uncertain what.—*A. M.*—Barleria flava.

PEAS.—*J. P. S.*—Your Peas may be protected in the event of frosty weather with Spruce branches.‡

PELARGONIUMS.—*Jonathan.*—Your young plants of Pelargoniums in a pit, that are in a growing state and forming flower-buds, may be shifted now; they should not, however, be allowed to become too luxuriant at this season, or they will not stand covering in case of frost. The foliage should be kept as dry as possible, and everything avoided that would tend to create dampness.‡

PINES.—*Philonus.*—Your plants ought to have a bottom-heat of from 80° to 84°, with a top-heat in proportion, when fruiting. Read Mr. Glendinning's Treatise.

PORTABLE HOT-BED.—*G. W.*—This is not made in England, but may be had through the Paris Nurserymen. The account was taken from the "Revue Horticole."

POTATOES.—*T. X.*—A good mealy Potato is the "Bread-fruit." A light rich soil will suit it best. The usual practice of placing the set upon the dung and then covering it in digging, produces the largest, but not the best-flavoured, Potatoes; they will be found drier and more floury if the dung is thoroughly mixed with the soil in digging, and the set simply planted in the furrow. A larger quantity of dung should, however, be put nearer the place which the row is to occupy than over the rest of the ground. The sets may be placed about nine inches apart in the row; the rows should be 20 inches distant, and the depth of the sets about seven inches.‡

RHODODENDRONS, MOSS ROSES, AZALEAS, &c.—*W. R.*—You may easily have these in flower by the end of March, but much depends upon the means you use for forcing such plants; whether you use bottom-heat and a high temperature at top, or merely keep them in a warm greenhouse; about a month (at that season) will be about the time required to bring them into bloom. But you must remember that the slower you force such plants the better; they are particularly apt to flower when first put into the forcing-house. ¶

ROSES.—*S. W.*—Subscription received. Answer next week.

SOIL.—*Leeds.*—The black mould from the heart of old trees would not be injurious to plants, but its advantage to them is uncertain; its action is something like that of finely-sifted peat.

SUGAR-CANE.—*M. D.*—There is no book such as you require, on the cultivation of the Sugar-cane. It must be remembered that Sugar is only one of the substances formed by the Cane, and the quantity which is formed will depend on the general health and vigour of the plant. When the Canes are manured you supply them with what is required by them, in the formation of several other substances besides sugar, and consequently increase the vigour of the plants. The ammonia and earthy phosphates in guano are useful to all crops when applied in proper proportions, particularly on poor soils; they render the plants more vigorous, and consequently increase the formation of gum, sugar, starch, gluten, etc. *E.*

TANK-HEATING.—*Amateur.*—We think we have not expressed any positive opinion that brick and cement tanks would prove too damp for greenhouses; we have only said that we fear they may prove so. If the body of the tank were sunk so low that the top, which is covered with slate or flags, is just level with the floor of the greenhouse, the liability to dampness (which chiefly penetrates through the sides) would, no doubt, be diminished; but then the tank would not give out the same heat to the house as if the sides were raised a foot or so above the level of the floor, as is usually the case: a great part of the heat that radiates from the sides would be absorbed by the floor. It is true, that in tanks the hottest current of water always floats to the top, and no doubt, therefore, the greater portion of heat escapes from the surface of the covering of the tank; nevertheless, by degrees, the water all becomes warm, and then heat will pass through the sides.

MISCELLANEOUS.—*J. J.*—If you will send us a specimen of the substance you call the Star-shot we will endeavour to tell you what it is.—*Mentor.*—To comply with your suggestion would be to extend these notices to a most inconvenient length; we often, indeed, fear already that our readers are weary of them. Besides it would not be worth while, except in special cases, and then we do it as part of our system, if we can find room. The same reason, namely, the inconvenience of letting them occupy more space, prevents our printing them in larger type.—*Ruricola.*—The canker in Cucumbers is produced by cold either at the bottom or top, or both. Mildew is owing to sudden chills and a low temperature. The most useful green-fleshed Melon is the Beechwood. For the manner of dealing with Thrips, see p. 619, 1843.—*Jas. Drummond.*—We should be glad to receive the notices you speak of; and perhaps the matter already printed may be used again.—*R. P.*—We find nothing in your paper of importance enough to publish it.—*Beta.*—The *last edition* of Dr. Lindley's "Theory of Horticulture" was published in 1840.—*A. L.*—Don't you know the husks of Maize when you see them? they are what form the packing of the Orange chests opened in Covent Garden Market.

*** As usual many communications have been received too late for answering this week.

DRAINING.—JOHN DAVIS, Mathematical Instrument Maker, Derby, begs to direct the attention of Agriculturists to a very efficient and simple Level he has just constructed, adapted especially for Draining. The private Farmer or the professional Drainer will alike find in it all that is desired. The Instrument fitted in a case, and sent to any part of the country —the price, 2l. 5s.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

EDWARD BECK informs Horticulturists generally that the Cisterns, Tanks, Shelves, Stages, Conservatory Tube, Flower-boxes, Edgings for Garden paths, &c., manufactured by him in Slate, may be seen in use at Worton Cottage, upon application to the Gardener (Sundays excepted).

The Agricultural Gazette.

SATURDAY, JANUARY 13, 1844.

WITHIN the last few years, many experiments have been performed on the subject of the SHED-FEEDING OF SHEEP, and their results have been so successful, that on some farms this way of managing the fatting sheep stock is now generally adopted.

Mr. Childers was among the first to direct attention to this subject. He has published the results of his experience in Vol. i., Part 2., of the English Agricultural Society's Journal. It is there stated that two lots, twenty in each, of Leicester wether hogs were selected, as similar in quality as possible. One lot was placed under shelter in a yard, and the other was folded in the field. They received the same kind of food, viz., cut Turnips *ad libitum*, half-a-pound of Linseed-cake, half-a-pint of Barley per sheep per day, a little hay, and a constant supply of salt. At first they consumed nearly the same quantities of food, eating each day about 19 lbs. of Turnips per sheep; but, after the third week, "there was a falling off in the consumption of the hogs in the shed of 3 stone of Turnips a-day," *i. e.*, 2 lbs. apiece; "and in the ninth week there was a falling off of 2 stone more. Of Linseed-cake there was also a falling off of 3 lbs. a-day," *i. e.*, nearly one-third of the quantity given. "The hogs in the field consumed the same quantity of food from first to last.

"The result of the experiment is as follows:—

20 Shed Hogs weighed		Increase.	20 Field Hogs weighed		Increase.
	st. lbs.	st. lbs.	st. lbs.		st. lbs.
January 1st .	183	9 —	184	4	—
February 1st .	205	0 21 11	199	8	15 4
March 1st . .	215	10 10 10	208	2	8 8
April 1st . . .	239	9 23 13	220	12	12 10
Total increase . . .		56 6			36 2

Consequently, the sheep in the shed, though they consumed nearly one-fifth less food, made above one-third greater progress." This result is confirmed by our own experience. Of three lots of sheep, one entirely covered in, another under a shed in the yard, and the third entirely exposed, all of them having one pint of Oats per sheep per diem, the first consumed, on an average, between Nov. 18, 1842, and March 9, 1843, 8 lbs. of cut Turnips and other roots per diem, and increased in live weight during that time 28½ lbs. per sheep; the second consumed 11 lbs. of the same food, and increased 25 lbs. in weight; the third consumed 17 lbs. of cut Turnips, &c. apiece each day, and increased in live weight 23 lbs. during the period. The several lots, it thus appears, did not differ so much in their growth as in the case reported by Mr. Childers, but there was a much greater difference in the quantity of food eaten by them; so great a difference, indeed, that were this result to be generally expected from a similar treatment, which, however, we by no means wish to infer, twice as many sheep might be kept in a fatting condition on the same quantity of food under perfect shelter, as under entire exposure.

We notice this subject now, as it is one to which the attention of the farmer may be usefully directed at the present time of the year.

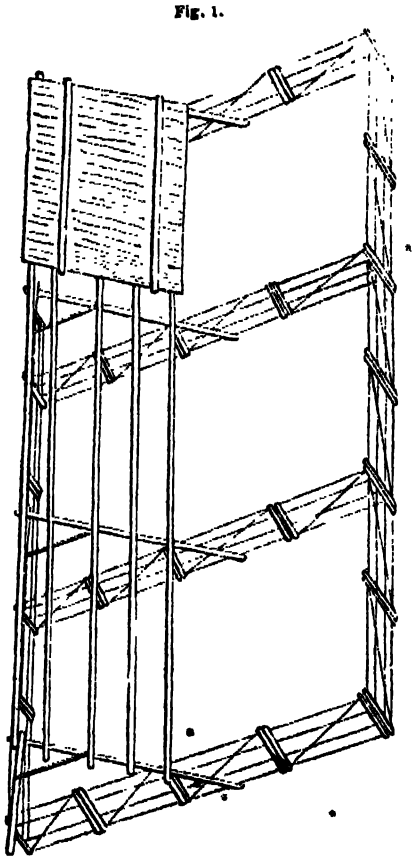
In exposed situations, during wintry weather, sheep on Turnips do not increase in weight—they often lose, as the experience of many can testify; and if the expense of carting the roots home and the manure back to the land, which is involved in the plan of house-feeding, be balanced by the additional value of the manure so obtained, as it probably is when the field is not very distant, then a saving of food and an increase in the production of mutton is the clear difference between shed-feeding and folding of sheep, in favour of the former. But there may be other differences between the two plans, as in point of healthfulness, &c., and to these we shall hereafter allude; meanwhile we may describe a very cheap and easily-erected form of shed with yard attached, which may be put up in the field, and thus very much reduce the expense of carting. The annexed woodcut is taken from part of a shed now in use containing 200 sheep. The cost of erecting the framework was 10s. per 100 feet in length, and the thatch, which in this case was read from a neighbouring pond, was laid on and tied down by two men in half a day; the labour of erecting 100 feet of shed sufficient for sheltering 100 sheep thus costing 12s. in all. To this must be added the cost of the materials of its construction, viz.:—

	£	s.	d.
100 Larch poles about 12 feet long . . .	—	—	—
6 dozen hurdles for the yards (see woodcut) .	—	—	—
	£—	—	—

These materials will last several years, and they may be taken apart out of the way at spring, and put up again every autumn at a cost of little more than one penny for each sheep to be sheltered by it. No charge is made for straw for thatch; it is the produce of the farm, and returns to the land, as it would were it used otherwise. The mode of erection is this:—Two Larch poles about 12 feet long, and crossing at their extremities, where they are nailed together, are thrust firmly into the ground at a distance of 15 feet; they thus form one with another rather more than a right angle (see Fig. 2).

A series of such couples arranged, as in fig. 1, at distances of 10 feet, form the skeleton of the future roof. A ridge pole is then placed so as to connect these couples; it lies in the forks made by their extremities crossing, and is nailed there. Four other side-pieces parallel to this, the lowest one being placed so far down the couples as to be within the height of a hurdle from the ground, are then nailed on each side, and the skeleton roof is completed. The thatch is now merely *laid on*, and two other poles, (see fig. 1), being laid above it, and tied through the thatch to the couples below it, hold it fast. Hurdles are now placed around and within, so as to form a series of little yards, 10 feet wide by 25 feet in length, of which nine are under the roof, and these being littered with straw are ready for the reception of 10 sheep a-piece. The outside hurdles should be wattled, so as to afford more shelter. The subjoined wood-cut represents one part of the shed completed, and the other part in its skeleton state.

Fig. 1.



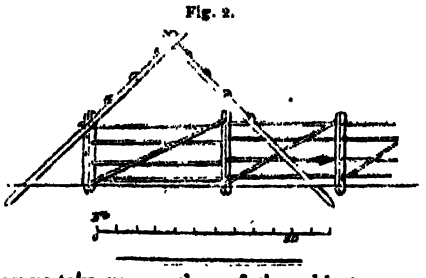


Fig. 2.

LET us take up another of the subjects suggested by the Prospectus of this Paper.

"No one man can be competent to deal with the multifarious questions affecting Husbandry, and the duty of the Editor of such a Paper as the *Agricultural Gazette* is to make known the knowledge of all. It is to practical farmers that the Proprietors trust for the means of carrying out their views, and not to the talents of any individual."

We are anxious to impress upon our readers the importance of a *widely-spread* Agricultural correspondence.

The many natural and other agents which affect the farmer vary, both in quantity and in kind, in the different districts of our country, to such an extent that the argument of any one who reasons merely from what he sees around him is rarely applicable to any other than his own immediate neighbourhood; so that a "Code of Agriculture" of universal application could be compiled only by a company of men, among whom every district of the kingdom should find its representative. Hence it appears to us, that a body of statements, each accompanied by the conditions under which it is correct, such as from a widely-extended system of Agricultural correspondence would ultimately accumulate, is the only source from which *any one* might, without fear, draw information for his own guidance as a farmer.

The produce of the land depends on four things: viz., the character of the soil, the nature of the climate, the skill and judgment of the farmer, and the amount per acre of his invested capital; of all of which it may be said, not only that the kingdom generally contains them in most various degrees, but that a district of only a few square miles cannot be named over which one of them is constant. And, obviously, that which is the best system of management, under one condition of these important agents, is not necessarily the best under any other condition; the same skill and sound judgment on the part of the farmer, which would sanction one mode of farming under one series of circumstances, would approve of another altogether different when those circumstances had changed. Many systems of farming may thus exist in a country, and do exist in this one, each very different from the others, and yet each justified by the circumstances under which it is placed. And the opinions of any Agricultural correspondent, however safely built upon facts, are not necessarily of general application, because that which is fact in his neighbourhood may not be fact elsewhere. Hence the importance—and, indeed, to an Agricultural Journal, aiming at usefulness, the necessity—of having a numerous staff of intelligent and practical correspondents widely spread over the kingdom.

And here, by the way, we may remark that it is a very common practice to compare, or rather to contrast, the farming of certain distinguished districts in the East and North of England, and in Scotland, with that of certain other districts in the South and West of the kingdom; but, though in such comparisons the results of farming may be accurately stated, yet it is manifest that no inference can justly be drawn from them as to the skill of the farmer, unless, at the same time, all that light be thrown on the question which would be afforded by a description of the soil and of the climate, and by a statement of the farming capital invested. So entirely, indeed, does the question—what is good farming depend for its answer upon these three circumstances, that we believe it will be found that the plan of farming which long experience has sanctioned in any district, however bad it may appear to others, is generally justified by the circumstances of the case. And, in saying this, we are quoting the opinion of Mr. Smith, of Deanston, who, perhaps, more than any other, struck boldly out from the beaten path when he commenced farming. Let us not, however, be understood to recommend that, in such districts, the mode of farming should remain unaltered, justified though it may thus be. Its faults may be remedied, and Mr. Smith's example may safely be followed, if the obstacles to improvement be first removed. The texture of a soil, its dependence upon a variable climate, and the amount per acre of the tenant's capital, are, to a great extent, all under control. The last depends, of course, upon the extent of the holdings; and the two former depend greatly upon the wetness of the soil, which may be removed by drainage. And when a farm has been improved in all these particulars, the same sound judgment which was before fearful of changing the mode of its cultivation will now recommend the adoption of another and superior plan. All that we wished to infer was, that a full statement of the Agricultural statistics of the districts referred to would put a stop to many of those comparisons which are drawn between them in order to prove want of skill against the farmers of some of them; for it would show that the differences in their Agriculture are often owing to the peculiar circumstances in which each is placed; and this would be beneficial, for it would tend to remove prejudices and jealousies from between those who, mutual interest certainly says, ought to be none other than good friends.

We hope, therefore, that our readers, in their correspondence with us, and with one another through us, upon the activity and practical nature of which we hang all our hopes of usefulness, will not only state their opinions, but the facts which justify them; and not only the facts, but the circumstances under which they have occurred.

There are many subjects upon which light would be thrown by an accumulated correspondence conducted thus. The differences existing between many districts

of the kingdom, as regards the results of farming, would receive their explanation, and such an explanation, probably, as, if acted upon, would greatly increase the Agricultural produce of the kingdom. The extent and nature of the influence exerted by climate, and by the other agents which affect farmers generally, would also be pointed out. And here we may express our satisfaction at seeing that the English Agricultural Society has offered a premium for the best Essay upon "The Influence of Climate on Agriculture." A detailed and statistical statement upon this subject would be a most valuable guide for—and, as we have already stated, a most useful restraint upon—future Agricultural writers.

We conclude, with the hope that, during the perusal of this article, our readers have kept in view, and self-applied the inference from our remarks, which we again repeat: It is essential to the usefulness of any Agricultural periodical, which is intended, not for local, but for general circulation, that it be supported by a widely-spread correspondence among practical men; it is essential to the usefulness of any such correspondence that it should not only embody facts, but state the circumstances also under which those facts occurred.

CULTIVATION OF ITALIAN RYE-GRASS, AND MODE OF CROPPING A STRONG CLAY FARM.

HAVING grown Italian Rye-Grass extensively and regularly upon different kinds of soil for many years, I am not incompetent to furnish some particulars respecting it, which may be of general utility.

The soils best adapted for it are deep alluvial and strong loams, and it succeeds well upon most descriptions of land. On those, however, which are light or stony, especially if upon Oolite, Chalk, or Limestone, and on any well adapted for the growth of Sainfoin, the crops of Wheat, after Italian Rye-Grass, are frequently defective, which probably might not be the case were the surface skimmed off by an extra share when ploughing the land; but it is not advisable to sow any considerable quantity of such land with Wheat after this Grass.

The produce is usually greater than that from any other description of artificial Grass, and the quality of the food is excellent for all kinds of stock; they prefer it to almost any other pasturage. When the seed is sown with spring Corn, the land should be stocked immediately after harvest, and the produce eaten off closely before November, avoiding treading tenacious soils in wet seasons. Very early in spring, the growth, after such treatment, if the land be in proper condition, is surprisingly rapid, so that those who have a crop of Italian Rye-Grass in their regular rotation of cropping always possess good and abundant keep for sheep after their Turnips are consumed, that being generally the most trying season for breeding and store stock. The produce should be well eaten off within a few weeks, and the land should be without stock for about the same time, alternating in this way during the spring, summer, and autumn. By such treatment, two fields of Italian Rye-Grass (one of the first and the other of the second year) will keep a much greater number of cattle and sheep, and in better condition, than the same quantity of land producing any other artificial Grass of the first and second year. It should never, when pastured, be suffered to run into seed, that being most injurious both to the quality of the produce and to the land also.

When intended to be mown, Italian Rye-Grass should be well eaten off after the preceding harvest, and not stocked in spring. The seed should be ripe when the crop is cut, and it should be taken up into sheaves immediately after the scythe, and set up ten or twelve together until sufficiently dry for being clean threshed. This should be done on a cloth in the field, with flails, or the heaviest and most valuable part of the seed would be lost. It should be put into sacks, carried into a barn and riddled, and spread and turned frequently, until perfectly dry, and should then be winnowed with a gentle blast, by which means the seed is of more than double the value of what is often sold; and with such treatment the produce has averaged more than four quarters per acre, and of the weight of about 10 stones per quarter. Half the quantity of this, that is requisite of foreign (or of ordinary English) seed weighing less than 7 stones per quarter, will yield greater produce. At the time of threshing, the crop should be spread and turned; and when stacked in good condition, it makes nutritious fodder, which is eaten by horses and cattle greedily.

When artificial Grasses or Clovers have failed from drought, or from abundant crops of Corn, they may always be most effectually renewed by sowing Italian Rye-Grass, which is very hardy, on the failing portions of a field after the first rain succeeding harvest; and this is a material advantage, as it insures a regular rotation of crops.

The following is the present state of this farm, with reference to Italian Rye-Grass and the crops succeeding it, the land being a strong loam upon tenacious clay, well underdrained with tiles. Three fields are regularly fallowed yearly after Wheat, well manured, and sown with Swedes or Turnips, the chief part of which are carted off for being consumed in fold-yards, and thus an unusual quantity of most valuable manure is made, both solid and liquid.

One field was sown with an imperial bushel of Italian Rye-Grass, 10 lbs. of white Clover, and 1 lb. of Parsley per acre, along with Barley, last spring, and will be pastured next year.

One field was sown as above, to be mown next year for seed and fodder, and after being manured according to usual practice, it will produce valuable after-math.

One field was sown with 10 lbs. of red Clover, a peck of Italian Rye-Grass, and 1 lb. of Parsley, for mowing for horses and cattle, and the second crop principally for sheep.

One field of Italian Rye-Grass and white Clover, after being pastured one year, remains for second year's pasture.

One field of Italian Rye-Grass and white Clover, after being mown for seed and fodder last year, and the after-math grazed, remains for second year's pasture.

Two fields of Italian Rye-Grass, one having been pastured two years, and the other having been pastured since the crop of seed and fodder in 1842, will soon be ploughed deep, and with a skim-share for Oats.

Two fields which produced Oats last year after Italian Rye-Grass, and one field which was sown with red Clover, and Italian Rye-Grass last year are now growing Wheat.

Three fields, now Swedes and Turnips, will be sown with Barley, Italian Rye-Grass, and Clovers, in spring.

The whole of the above have now a good appearance, and the same system has been practised for several years with increasing advantage.

The arable land of the farm consists of 16 fields as above: viz., two courses of six and one of four in alternate rotation, and the same field is sown with Red Clover, for being mown, only once in 16 years. I also grow Italian Rye-Grass, with white Clover for pasture, and with red Clover for being mown, on two other farms regularly, and have long ceased to sow any other variety of Rye-Grass.

Objections have been made to Italian Rye-Grass besides that mentioned at first, it being alleged that the land, after the succeeding crop of Corn, is frequently foul with Couch and other inferior Grasses; this is the natural result when genuine seed has not been sown, or when the land has not been properly cleansed. My land, after the first and second crops immediately succeeding Italian Rye-Grass, is generally as clean as though the crop had been sown after fallow; and I have never failed of having abundant crops of Corn, and these of good quality, after Italian Rye-Grass. I shall be happy to show my crops to any of your readers, or to give further particulars with reference to this communication.—*John Parkinson, Ley Fields, Newark, Notts.*

AGRICULTURAL EXPERIMENTS.

(*Continued from p. 11*).

Erratum, p. 11, col. *a*, line 21, from the bottom, *for* 166*l.* 15*s.* 10*d.*, *read* 6*l.* 15*s.* 10*d.*

I NOW proceed to describe some experiments upon Corn, which, however, were not of a decisive character, for they were tried either only in single proportions or on different soils, and therefore, though the results are extremely discouraging, it does not follow that the manures are bad and not worth further trial. Other proportions, or, indeed, the same, under other circumstances, may still be found advantageous. The mode in which these results were ascertained was as follows:—six perches of land were selected from each manured portion, and the produce both of Straw and Corn was carefully measured and weighed, and from these data compared with the produce of an unmanured adjoining portion of equal extent; the profit and loss per acre was computed, after deducting the cost of the manure. It is necessary to enter into these minute details, for the purpose of showing what reliance may be placed upon the accuracy of the experiments. One conclusion, at least, may be safely drawn from those experiments, and that is, that in Agriculture, as in all other natural sciences, some phenomena will occur which we must be content not to understand. Accurate analysis, perhaps, might assist in solving the problem, why the same quantities of the same manure applied to similar soils under similar circumstances should produce such very dissimilar effects; but for that purpose the soils must be analysed at the time of sowing, for their constitution will be inevitably changed by the growth of the crop, and by the accidents of cultivation. And on general principles it would be hard to account for the Guano being more beneficial to a more fertile soil, than to one that is less fertile, and harder still to say why, when 3cwt. increases the produce of Corn by four bushels, 2cwt. diminishes it by more than half that amount. Nitrate of soda presents another instance of irregular action, for 1cwt. seems to have injured the crop; less Corn grew where it was used, and much less straw; but when one-fourth more was added the injury was not increased, but the produce was in a remarkable degree; amounting to 8 bushels of Corn and 23 trusses of straw more than on the unmanured part of the same field; the quality of the land, however, was very inferior to that on which the other experiment was tried. Sulphate of ammonia, the only other manure that repaid its cost, exhibited no such anomalies; it is true it was tried in only one proportion on two sorts of Corn, but in both instances a small quantity produced good effects, especially upon the Barley, and better may be anticipated from larger measures of it, for some experiments which I have tried on a smaller scale, for the purpose of testing more accurately the power of the manure, seem to show that when applied to Corn its success is—not as on grass—nearly in an inverse ratio to the quantity employed, but in some proportion to the increase of quantity—not, indeed, in any definite proportion, but so that the increase of produce is on an ascending scale. Three small portions of spring-sown Wheat were watered with a solution of 1 lb. of sulphate of ammonia in 8 gallons of water, which is at the rate of much more than 60 lbs. to the acre. The first was watered once, the second twice, the third three times, with an interval of about 10 days between each watering. It was intended to give additional doses to the remainder, but the Corn grew so rank, that it was feared it would die of plethora, and the thickness of the herbage intercepting the liquid intended for the roots, it began to grow rusty, and the deep green verdure being disfigured with brown spots, it seemed to be a complete failure. Nevertheless, the ears shot up vigorously, and were not laid like some of the adjoining corn by heavy thunder-showers, and at harvest 12 ears being taken from one end of each row, the Wheat they contained was weighed, and the results were as follows:—

Watered once the weight was	.	696 grains.
,, twice ,,	.	1330 ,,
,, thrice ,,	.	1438 ,,

In the first case the average number of stalks upon each root was six; in the others, eight. Compared with the unmanured, a bushel of it would weigh about 1 lb. more. A similar ascending scale of value is more strikingly exemplified in some experiments on Indian Corn. In all of them several of the ears were very defective, and not half clothed with grain. It is, therefore, as in the last instance, not to the positive quantities that I wish to call your attention, but to their relative productiveness, as compared one with another.

| | | |

rtantly, for the ashes will supply them with the mineral substances they want, which the soil does not contain, viz., gypsum, phosphate of lime, potash, common salt, and magnesia. Oats contain more potash than all other Cerealia, and thus we see that they will succeed after a manure of either fresh or even extracted wood-ashes, which latter generally contain a good deal of potash, or at least silicate of potash. Rape is very rich in potash, soda, chlorine, and sulphuric and phosphoric acids, on which account it requires a plentiful supply of good dung, which contains a greater amount of these substances than most of the mineral manures. It is, however, also improved by a simultaneous manure of marl (as shown by every day's experience), by which it appears the more clear, that the dung does not entirely supply its want of mineral substances. Dung will supply Rape abundantly with nitrogen, which this plant is so much in need of, but even this can be effected by some mineral substances, viz., by any of the nitric or ammoniacal salts, as proved to me by experiment. Beech-trees will not succeed in sandy soils, whilst Pine will succeed there very well, and for this reason; the former tree contains much potash, soda, magnesia, &c., substances which therefore are required for its growth; whilst Firs require but very little of these substances, and consequently will succeed in sandy soils, which in the main do not possess these mineral substances to any considerable amount. The Fumitory (Fumaria) contains a great deal of potash, on which account we always find this shallow-rooted plant in localities whose surface is rich in that substance. The Nettle, the Mugwort, Coltsfoot, the Thistle, and the Burr, are also rich in potash, but their roots penetrate deep into the soil, and thus we find them in places where the subsoil contains much potash. The so-called Salt plants, (Salicornia, Salsola, &c.) succeed only in soils superabundantly rich in common salt, and we find in them a greater amount of potash than in any other plants. The Rush (Juncus), appears always in a soil rich in potash and manganese, and it is a proof of its requiring much of these substances for its nourishment, that they enter largely into its chemical composition. The chemical analysis of the Lupine has convinced me that it contains much iron and phosphoric acid, and I find also that it succeeds best in localities whose subsoil is rich in these mineral substances. If we manure a sour moorland with a mixture of sulphate of potash, gypsum, phosphate of lime, and magnesia, common salt and fine quartz gravel—(substances which do not neutralise the acidity of the soil), we shall find that the plants afterwards grown on it will prosper, and this proves that these are the mineral substances which nourish the plants, and we shall also find these substances entering into their chemical composition. If mineral substances acted merely as solvents of the humus, or merely as stimulants of the vegetative process, they would be equally useful to all plants; but the contrary is the fact; gypsum, for instance, will improve Leguminous plants, whilst nitric salts will have no effect at all on them. The above examples, and many others which I could cite, prove, I think, most evidently, that besides carbon, hydrogen, oxygen, and nitrogen, mineral substances also are required for the growth of plants.

The following general remarks are yet to be added, relating to the manuring with mineral substances. Every mineral substance which is contained in a plant is necessary as a manure for that plant, in so far, namely, as it is not contained in the soil in a sufficient quantity. No mineral substance, however, is required by plants in large quantity; and because only a very small quantity is found in some of them, the opinion has arisen that they are but adventitious ingredients, not essential component parts of plants. One of the reasons why the application of mineral substances has not produced the expected result, is, that sufficient notice has not been taken that plants do not require, nay, cannot bear, a large quantity of some mineral substances. If, for instance, a mineral substance is very easily soluble in water, 10 or 15 lbs. per acre more of it than is necessary will produce an unsatisfactory result, as the plants will then be compelled to receive more than they are in need of. On the other hand, mineral substances which are soluble in water with great difficulty may, without danger, be used in greater quantities, if they produce the desired effect. If, therefore, we wish that mineral substances shall act beneficially as a manure, the degree of their solubility in water is especially to be taken notice of. If, moreover, mineral substances are to be useful, it is also always necessary that the soil be not deficient in humic acid, because the latter has not only to act as the transferring medium of mineral substances into the plants, but it is also from it that plants have to obtain the carbon, which (as far as weight is concerned) is always the chief component of plants.

(To be continued.)

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. I.

Every human being is directly or indirectly dependent upon the vegetable world for the food necessary to support life.

The universality of this important fact places Agriculture among the highest of useful sciences, and the influence it exercises over the welfare and happiness of mankind is the result of its paramount necessity.

In a primitive state of nature, a bountiful and all-wise Providence has abundantly supplied every living thing with the means of subsistance. Civilization and its attendant luxuries, and the rapid increase of population, have created more wants among mankind; and hence the necessity for increasing our means of obtaining food—among which the application of Chemistry to Agriculture has in modern days excited considerable attention.

By Agricultural Chemistry is meant—Firstly, The Chemical analysis of soils; by which the elements from which plants derive their means of growth and supporting life may be, so far as the soil is concerned, clearly defined and understood.

Secondly, The chemical constitution of plants; by which correct notions of the adaptation of the soil to the plant may be founded.

Thirdly, The chemical examination of manures, or the food of plants; by which a correct system of their application to the known condition of the soil and the known constitution of the plant may be established, and also the best means of retaining or increasing their fertilising principles.

In the following papers I propose to examine these three heads separately, pointing out, in the most intelligible manner I can, the means by which the farmer can successfully apply chemical principles to the practice of Agriculture.

Part I.—Of the Chemical Analysis of Soils.

There can be no doubt that a knowledge of the chemical constituents of soils is a most important preliminary inquiry in the science of Agriculture. The common division of soils into "light," "heavy," "sandy," &c.—a division based upon the practical knowledge of the farmer—is sufficient for ordinary purposes, but a more exact and intimate examination is necessary for the application of Chemistry. There are degrees in each of these divisions which must necessarily escape the most acute observation, and analysis can alone afford the information necessary to found a system of scientific Agriculture.

I have reason to believe that one of the most serious obstacles to the farmer in entering upon this inquiry is that which is presented to him in the outset, in the difficulties he encounters in gaining a correct chemical knowledge of his soils. I hope to show that this difficulty is more imaginary than real, and that much very valuable information may be obtained without any knowledge of Chemistry whatever, by the mere exercise of ordinary tact and a little extraordinary patience and perseverance.

Sir Humphrey Davy more than 30 years ago, in his admirable work upon Agricultural Chemistry, pointed out how this could be done. Within the last few years, what is called Organic Chemistry, or the analysis of vegetable or animal structure, has made rapid strides in the march of improvement; and hence the more easy application of chemical science to that of Agriculture. But it is erroneous to suppose that it is necessary for the farmer to have an intimate acquaintance with Chemistry; and much difficulty has been raised in making him believe the results of science, from an impression of this kind. The knowledge he requires is the means of applying the discoveries of others to the improvement of his system of farming. The chemist can explain to the farmer, that certain plants require certain food, and although the statement of the chemist is founded upon his knowledge of the ultimate elementary structure of both, it does not follow that it should be necessary for the farmer to undertake the analysis of Wheat or stable manure. He may be taught how to fix ammonia without entering into abstruse detail or discussing difficult problems in a science of acknowledged difficulty.

The inquiries of the chemist render a perfect knowledge of the science necessary; but while he is instituting lengthened analyses in his laboratory, and deducing important truths from them in his study, it is as well that the farmer should be testing the correctness of his inferences by subjecting them to the test of careful, of sound, and useful experiments.

All soils are divisible by a very simple process into three principal parts.

The first contains coarse gravel and sand (generally composed of flint and chalk), and undecomposed vegetable fibre.

The second of fine sand, called by chemists, silex.

The third of a fine powder, called by Sir H. Davy, "impalpable matter," and which generally consists of the following substances, in variable proportion.

Firstly. Aluminous earth; the principle which gives to clay its peculiar character, and upon which its value in making earthenware depends.

Secondly. Decayed vegetable matter, which is known by the term humus. This principle generates an acid termed humic acid, by its union with oxygen; and this acid again unites with lime and other earths, forming what are termed humates.

These humates are very insoluble, but they perform an important purpose in vegetation, by their decomposition setting free the carbon of the humus, which is one of the elements in the food of plants.

Thirdly. Silica, which is an earthy substance, formed by the union of an elementary principle, called Silicon, with oxygen. In its pure form it is known as quartz rock. The difference between the silica of the impalpable matter and the silex, or sand, above mentioned, is simply that the one is crystallised in the form of minute grain or sand, and the other is what is termed amorphous, or uncrystallised.

The same substance frequently occurs in Chemistry under different forms, for the obvious reason (as in the above case) of being more easily appropriated by the roots in the organisation of the fabric of the plant. United with the alkali and potash, silica forms the substance upon which the stiffness and brittleness of the stalks of Corn and other grasses depend. It is from the union of these materials, also, that this well-known substance—glass, is manufactured.

Fourthly. Various salts; of which carbonate of lime (chalk), carbonate of magnesia, muriate of soda (common salt), carbonate of potash or soda, and sulphate of lime (gypsum), are the most frequent.

These ingredients are all of them more or less discovered in plants, in which they perform important purposes in the nutrition of animals that feed upon them. Thus chalk is necessary to form bone; soda and potash, bile; muriate of soda, milk.

Fifthly. Most soils contain animal matter which nourishes the plant; and

Sixthly. A variable proportion of the oxide of iron, which is an essential element in the blood of animals.—*C. R. Bree, Stowmarket.*

(To be continued.)

Home Correspondence.

Leases.—Give to the farmer who has sufficient capital a certain term of interest in the soil which he cultivates, and then he will not only be justified in laying out his capital in its improvement, but he will exert all his energy in increasing its productiveness so as to insure the greatest return to him for his outlay. The length of term to be given should be dependent upon the extent of the improvements which the land requires. When land is let for building on, a term of 60, 80, or 90 years is granted, to indemnify the speculator for the expenses of bricks and mortar, and the risk he is subject to; just so should it be with the farmer. When there are expensive improvements and risk to be sustained; if the land is wet and has to be thoroughly drained, &c.; if the nature of the soil requires to be altered so as permanently to improve its texture; if roads have to be made; if additional buildings for the necessary accommodation of stock to consume the increased produce require to be erected; if foreign manures be required, and a new and more perfect mode of culture be necessary, such a length of lease, according to the peculiar circumstances of the farm, should be granted, as will induce an enterprising tenant to embark his capital in the permanent improvement of the stock.—*J. F.*

Mode of Planting Wheat.—I quite agree with the statement Mr. Morton gave in your last, of the advantage to the Wheat crop of thin and regular sowing. Plants that are put into the ground at equal distances produce a more uniform and a greater crop than when they are planted irregularly. Wheat will yield more if drilled than if sown broad-cast, and more when dibbled than if drilled. No kind of seed which the farmer uses should be planted more than two inches deep. Perhaps one inch is better than two, when the soil is stiff and clayey. The lighter the soil is, the deeper we may plant our seed.—*T. C. M.*

Agricultural Education.—There has been for several years a general opinion expressed that a knowledge of the sciences should be combined with agriculture, and that the practical farmer, by possessing a complete knowledge of all the sciences, bearing either directly or indirectly on his business, would be a much more effective agriculturist both for himself and for the community at large; and by bringing a greater amount of knowledge to bear on all his operations, he would obtain a greater return from his capital employed. It is also generally lamented that the means of acquiring scientific agricultural knowledge are not more generally within the reach of every man who intends to give himself up to an agricultural life. Most farmers, however, think that they themselves can give their sons all the agricultural education that is necessary to make them able to earn a livelihood; and, therefore, though they may have the means of acquiring a knowledge of the sciences which tend to illustrate the phenomena exhibited by nature in their business, it is more than probable that not one in a thousand of the farmers' sons of the present day would be sent to receive the scientific instruction if it cost them but a mere trifle. People must first feel their wants before they can be anxious to go out of their beaten track to get them supplied.—*A Farmer's Son.*

Varieties of Wheat.—The relative value of the several varieties of Wheat, as well as of all other plants which the farmer cultivates, ought to be carefully attended to. There is no doubt but vegetables, like animals, will only and always reproduce their varieties, and therefore the farmer should be as careful in selecting his seed Wheat, &c., as he is in selecting his sheep or stock to breed from. The largest and best grain will produce larger and better grain than the seed taken from smaller grain, the produce of an inferior crop; this is on the principle which we believe to be undeviating in nature, that all things reproduce their kind. Bearded Wheat, or what is called Rivets, is said to be most natural to moist clayey land; and beardless Wheat to dry light land. The white varieties of Wheat form and succeed better in very dry seasons, or on very dry, warm, sandy soils, than the red or brown varieties. The red and brown varieties seem better fitted for tenacious clayey soil than the white varieties are.—*A Practical Farmer.*

Flour of Wheat.—This Table shows the quantity of first, second, and third flour produced from Wheat of various weights per bushel, also the quantity of bran and waste. The numbers of parcels and quantities of each are also given. This is a return from Mr. Mitchel's mills, Cupar, Fifeshire, in July, 1840, the produce of 1839:—

Lots	No. of bush.	Wght. per bush.	Flour. First	Flour. Snds.	Flour. 3rds.	Flour. Total.	Bran	Waste	Total.
		lbs.	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.
4	480	56	—	45.6	—	45.6	9	1.2	56
5	760	56	40	5.5	2.3	47.8	9	1.2	58
6	1400	56	41	5.5	2.2	49	8.8	1.2	59
7	1600	56	42.5	5.5	2	50	8.8	1.2	60
15	2196	61	44	5.2	1.8	51	8.8	1.2	61
7	1088	62	46.5	3.5	1.5	51.5	8.5	1.0	62

Cost of Drain Tiles.—The cost in Lincolnshire of making drain-tiles 13½ inches long, 4½ inches wide, and

6 inches high, outside dimensions when burnt is, for digging, wheeling, turning, and grinding the clay, 3s. per 1000; for moulding, 2s. 6d.; for burning, delivering, and for waste, 3s.; in all 8s. 6d., exclusive of coals and loading. In 1831 one million and a half of these tiles were supplied to one land-owner, who was charged 22s. 6d. per 1000 for them by the maker. When the expense of 1s. for grinding is added to 2s. 6d. for moulding, making in all only 3s. 6d., the slight advantage of machinery now in use to effect these processes will appear. Where its application actually does reduce the cost, it can only be by reducing the 3s. 6d. paid for moulding and grinding, for the other charges remain the same. Few use a bottom or tile sole. There are tile works now constructing where it is proposed to take the clay as soon as dug, at any season of the year, pulverize it without adding water, and mould it into tiles, all by one operation by pressure; and at one quarter of an inch thick the tiles are of sufficient strength; they have inward projections to dispense with the use of tile soles. Pipe tiles, and those of other shapes, as well as sewer tiles, are to be produced of equal comparative strength.—*Anonymous.*

Experiments upon Turnips at Rothamstead, Herts.—Soil, heavy loam. Three previous crops, Wheat, Clover, Wheat without manure. Sown July 24th. Weighed December 19th. Space occupied by each experiment one third of an acre, the weight of Bulbs per acre are given, all dirt, root, and top being completely removed. The Turnips in Nos. 6, 15, 16, 17, 19, and 21, were safe from the fly a week before the others, and maintained a striking superiority over them during the first two months:—

	Tons.	Cwt.	Qrs.
1. Horse dung, 12 Tons	9	9	2
2. No Manure	4	3	3
3. Rape Cake, 14 bushels, 50 lb. per bushel	8	4	3
4. Rape Cake, 12 bushels; Yeast, 2 bushels	8	1	1
5. Yeast, 8 bushels	10	19	2
6. Super Phosphate of Lime, 4 bushels; Phosphate of Ammonia, 12 lb.; Yeast, 4 bushels	11	14	1
7. Phosphate of Ammonia, 56 lb.	6	18	2
8. Super Phosphate of Lime, 4 bushels; Rape Cake, 8 bushels	12	2	2
9. Super Phosphate of Lime, 2 bushels; Rape Cake, 12 bushels	10	8	2
10. Super Phosphate of Lime, 4 bushels; Phosphate of Ammonia, 20 lb.; Rape Cake, 4 bushels	11	7	3
11. 2 bushels Super Phosphate of Lime; Phosphate of Ammonia, 40 lb.; Rape Cake, 2 bushels	10	12	0
12. 2 bushels Super Phosphate of Lime; Phosphate of Ammonia, 10 lb.; Rape Cake, 8 bushels	9	15	0
13. 6 bushels Super Phosphate of Lime; Phosphate of Ammonia, 20 lb., Rape Cake, 6 bushels	11	16	0
14. 3 bushels Super Phosphate of Lime; 2 bushels Phosphate of Magnesia	12	0	1
15. 3 bushels Super Phosphate of Lime; 2 bushels Phosphate of Potash	11	15	0
16. 3 bushels Super Phosphate of Lime; 1 bushel Phosphate Magnesia; 1 bushel Phosphate Potash	11	17	2
17. 3 bushels Super Phosphate of Lime; 1 bushel Phosphate of Potash; 1 bushel Phosphate of Magnesia; 20 lb. Phosphate of Ammonia	12	15	0
18. Super Phosphate of Lime, 6 bushels; Yeast, 6 bushels; Rape Cake, 2 bushels	12	14	3
19. 7 bushels of mixture, composed of 60 parts Super Phosphate of Lime; 40 parts Rape Cake; 4 parts Phosphate of Ammonia	11	19	2
20. Unburnt Bones decomposed by Sulphuric Acid, 7 bushels; Rape Cake, 7 bushels	11	15	0
21. 7 bushels Super Phosphate of Lime	12	3	2

—*J. B. Lawes.*

Lichens eaten by Squirrels.—Perhaps some of the readers of the *Chronicle* are not aware that the squirrel feeds greedily upon Lichens. I was not aware of this until a few days ago, when my attention was attracted by one running up an Arbor vitæ, with a piece of an Oak-branch about a foot long. When it had ascended about half-way up the tree, it began to eat the Lichens from the branch, which was densely crowded with them. I had not stood two minutes when it took fright at me, and dropped the branch. I examined it, when I found about 6 inches in the centre of it quite clear of Lichens, and part of the bark also bit off. The Lichen was the Ramalina fraxinea.—*J. Drummond, Blair-Drummond.*

The Markets.—I am glad to find you resolved to give market prices on good authority. Such a plan deserves every encouragement; for, as they are now published, they are much worse than useless. I cannot, however, compliment you upon the manner in which it was done last week. Nothing can be more absurd than Foreign and English White Clover, 74*s.* to 84*s.* I will defy any one to buy it at that price. I know that some second-rate of last year's was sold to-day at 90*s.*, and some first-rate was sold on Monday at 120*s.* For Trefoil no return is given, though there is plenty of it ranging from 30*s.* to 40*s.* English Red Clover is wrong, too; and you have actually no return for Tares, though plenty are to be bought. However, time will improve, I dare say.—*Peter Schlemihl, Jan.* 10.——Another correspondent complains of the unbusiness-like form in which Wheat is given. "For instance, the price of Wheat from Norfolk, Lincolnshire, &c., is stated at 47*s.* to 54*s.*; but, from the form of the report, it is quite impossible to know whether White or Red Wheat is meant. Of course the value of reports depends entirely upon their accuracy and fulness; and now that your Paper aims at an Agricultural character, accuracy and fulness will be looked for in that department."—[In reply to these criticisms, we can only say that the reports are given on the authority which we quote, and that we have done all that we believe it possible to do to obtain correct returns.]

Management of Manure in Farm-yards.—We have been requested by Mr. Harrison, of Devizes, to publish a letter on the Management of Manures, which he addressed to the Royal Agricultural Societies of England, Scotland, and Ireland, some months ago. It was at that time published in many of the Agricultural papers, and on that account we the less regret our inability from want of room, to insert the whole of it. Mr. Harrison recommends that, instead of allowing the manure to remain on the surface of the yards, it would be better to form it into ricks round the tank, so that it may be supplied with the liquor during the time of making. He recommends that all weeds, cuttings, and parings from roads, deposits in ditches, rubbish from gardens, &c. &c., should be carried home, and be deposited in these manure-ricks, according to the following directions, viz., "A layer of stable-dung, 1 foot thick, salted; a layer of vegetable matter, 6 inches thick, limed; a layer of stable-dung, 1 foot thick, salted; a layer of vegetable matter, 6 inches thick, limed; a layer of stable-dung, 1 foot thick, on the top of this fifth laying; saturate with the liquid from the tank in sufficient quantity to pass through the whole. Begin again, and repeat the layers as before with the dressings, and make the ricks to any size, the larger the better; then cover them up close with long dung or straw (earth would be better) to keep in the ammonia and prevent the rains from penetrating." Mr. Harrison justly remarks, that "A *clean farm* is not to be obtained without attending to the use of manure properly decomposed, and also to that of *liquid* manure, as these take no filth to the land." He states, in conclusion, "*Complicated recommendations* for a general plan to be adopted in the manufacturing of farm-yard manure would, I am convinced, from the experience I have had with Agriculturists, have no general effect." And he says "from experience" what we were at first inclined to doubt, that the plan he has suggested is very plain and simple, so as to be in the power of any one to adopt; and that those who may feel inclined to try it will find their manure doubled by it in value.

Bones.—A few months back I addressed you on the comparative merits of boiled and unboiled bones. In your reply you appeared to give a decided preference to the former, notwithstanding the enormous loss of grease in the process of boiling—say 50 per cent. I have since had a little conversation with a respectable Scotch farmer from Roxburghshire, from whom I elicited some interesting facts bearing on the above subject, although he was not aware at the time what my object was. I inquired if bones were still in great estimation in his neighbourhood? He replied that, for the last three or four years the farmers had neglected them altogether, in consequence of little or no effect being produced by them on the Turnip crop, and that they were now glad to return to the farm-yard for their supply of manure. He further added that, five or six years ago, bones only were used for the Turnip crop, and with the most beneficial results. He could form no idea as to the cause of the change which had taken place, nor could he inform me as to the weight per bushel of the bones now and five years ago; but he told me that on the first occasion of bones being used in his immediate neighbourhood, he uncovered a few yards of the drill line after they had been sown some days, and found them covered with an exudation having the appearance of hoar frost (his own expression), and which was, of course, the essential part, viz., fat and grease. About two years ago, when bones were found not to answer, he examined them, as before, but no "hoar frost" was to be found; the examination was repeated several times, but still no exudation was perceptible—he could not account for it. Now, to me, the reason is very obvious: the first were genuine unboiled bones, full of marrow and grease—hence the appearance of "hoar frost;" the last were boiled and stewed till not a particle of fat or grease was left, and consequently there was no "hoar frost." I am not a learned Chemist, and may be wrong in the conclusion I have drawn; but I am open to conviction, and shall feel much obliged by any information on the subject.—*E. R., Halifax.*

Artificial Manures.—If you would take the trouble to ascertain what the real facts are regarding the many new-fashioned manures which farmers are advised to use, you would be doing us a real service, and also how to tell whether the good ones are adulterated. I have tried my hand a little at these things, but I do not feel at all sure that I have ever got my money's worth back again, to say nothing of profit. However, I do not want to set any body against them; only, I want to learn whether they are good for anything or not, and if so, for what? We farmers have no money to waste in fancies; and although we should be glad enough to get better crops if we could, yet we should be also thankful for advice how to proceed. Now that your Paper is started for our information, you should not lose time in making us acquainted with the *truth* in this matter.—*Timothy Kippax, Farmer.* [We perfectly agree with this correspondent on the importance of the subject he names, and have already taken means to do that which he desires. We shall examine all the manures that are on sale, and state every *fact*, for or against them, that we can collect.]

Clover Dodder.—Having reason to believe that the Dodder found upon Clover raised from Indian seed is not the same as that which has been so destructive of late in the Clover-fields of East-Anglia, I should feel much obliged to those farmers, and others, who may have gathered either of those Dodders if they will send a small portion of the plant to me, by post, directed to "St. John's College, Cambridge." A statement of the person from whom the Clover-seed was obtained, and the date of its purchase, would be a valuable addition to the specimens. If this information is afforded to me, I have reason to hope that I shall be enabled to trace the seeds of the weed to their native country, and point out a mode of avoiding it in future.—*Charles C. Babington.*

Application of Manure to Water Meadows.—The following are some particulars about our crops of Grass in the Holm:—By means of a water-cart we watered the lower Holm with the manure from the cesspools connected with the mill, diluted with two-thirds water. This, with the exception of the banks of the cut and river, was done in March. The upper Holm we manured with Guano at the rate of 3 cwt. to the acre, and it was irrigated previous to the application of the manure, while that manured with the night-soil and urine was irrigated subsequent to manuring. To prevent the water from washing away the manure, it was dammed up and allowed to sink into the land, which it soon did, as the soil is alluvial and sandy. I believe scientific irrigators do not consider this plan so good as allowing it to flow over without stagnating; but this would have wasted our manure, and the plan succeeded so well, that we had an abundant crop by the 1st of June. We did not cut until the 8th, on account of the unfavourable weather before that time; but were then so highly favoured as to harvest the whole (14 acres) in less than a week. We had a crop of sixty cart-loads of about 13 cwt. each. We then immediately irrigated again, and cut our second crop (40 cart-loads of 13 cwt.) in eight weeks from the first cutting. As soon as the second crop was secured, we manured the banks of the cut and all the more impoverished parts of the field with a good coating of dung from the stable-yard and cow-midden, which was overgrown and out of sight in about a fortnight. Our cesspools connected with the mill are now so large and well supplied with valuable manure, that I hope we shall have little or no occasion to use Guano, except upon those parts of the field which we cannot reach with the water-cart. In addition to the urine and night-soil flowing into these cesspools, we turn in the ammoniacal liquor from the gas-works, which we find to be a powerful stimulant; and we fix the ammonia by putting in a daily supply of a sulpho-phosphate of lime (from bones), which some of the manufacturing chemists produce in large quantities and sell at a cheap rate, and which we find far more effectual for the purpose than either gypsum or sulphate of iron, and far less dangerous and less troublesome than sulphuric acid.—*T. G.*

Societies.

HIGHLAND AND AGRICULTURAL SOCIETY.

The monthly meeting in the Museum was held on Wednesday, Jan. 3, under the presidency of the Earl of Roseberry. The first communication was from Dr. Morison, of Banchory Devenick, descriptive of a guard for protecting the piers of bridges over rivers against accidents from floating timber. Sir John Graham Dalyell then described the model of a machine for weighing cattle and sheep and other commodities, constructed by Mr. John Craig, Glasgow. This machine resolves itself into a steelyard. One pound in the scale balances one stone on the platform. Sir George S. Mackenzie exhibited to the meeting a chondrometer, made by Mr. Adie, optician, Edinburgh. Mr. Borthwick, of Crookston, then read a communication from Mr. M'Lean, Braidwood, near Penicuik, in continuation of experiments made by him in 1842 with certain manures. One field of Grass that had been top-dressed with saltpetre, nitrate of soda, salt, soot and earth, ashes and earth, and soot, and intended for Hay, was obliged to be pastured by the dairy stock, along with other pasture lying contiguous. Throughout the season the cows seemed to relish the Grass in all the pasture alike, except that dressed with soot, in which they allowed almost all the Grasses to run to seed, and the Clover did not seem to thrive so well upon it. Another field of inferior soil was top-dressed, an acre to each, with sulphate of ammonia, guano, guano and sand, soot and earth, nitrate of soda, salt, urine, saltpetre, and a portion left without any top-dressing. The Grass was made and cut into Hay, and the general results were, that the portion which had no top-dressing yielded only 3*l.* worth of Hay, at 8*d.* per stone of 22 lbs., whereas each of the other portions yielded nearly double that value, the greatest being derived from the soot and earth, mixed in the proportion of 15 bolls of soot to 10 cart-loads of earth, the Hay after which was worth 6*l.* 2*s.* 8*d.* The crop of Oats this year, after Grass that had been top-dressed with 30 cart-loads of farm-yard dung, was 20 per cent. superior to that on portions top-dressed with 15 cart-loads of farm-yard dung and various sorts of artificial manures, especially where the sulphate of magnesia, carbon, nitrate of soda, sulphate of ammonia, and urine were applied. A description of a model of a single horse cart, constructed by Mr. James Dryden, Builder, Saunders-street, Stockbridge, Edinburgh, was read by Mr. Dewar. The improvement intended to be attained by this model consists in placing the cart with its load upon the axle farther forward or backward than its ordinary position, by means of an adjusting screw worked behind the cart, according as the load is to be drawn up or down hill, so as always to retain the same weight upon the horse's back. A statement as to the mode of erection and tenure of cottages for labourers and tradesmen on Mr. Hope Johnstone's estates of Annandale, by Mr. Charles Stuart, of Hillside, factor on these estates, was read by Sir Charles Gordon. The last two communications were read by Mr. Milne—the one affording a comparative view of the value of moss land in its improved and unimproved state, and experiments made thereon with different manures, by Mr. Carstairs, of Springfield, near Penicuik; and the other detailing experiments with the same class of manures on the farm of Auchencraw Mains, in Berwickshire, by Mr. Edward Makins. Mr. Carstairs states, in regard to the improvement of his moss land, that about 30 years ago, when it consisted of 233 acres, at an elevation of above 800 feet above the sea, it was let for 10*l.* a year, or 9½*d.* per acre, for sheep pasture, and then inhabited by only 5 persons. In 1843, two thirds of that quantity (the remainder being deep flow moss) yielded from 70 to 80 small stacks of Corn,

containing from 5 to 8 bolls each; from 2000 to 3000 stone of irrigated meadow Hay; from 2000 to 3000 stones of Clover Hay; and from 500 to 600 bolls of Potatoes. There are 8 or 10 cattle, 10 horses, old and young, and from 40 to 50 persons living on the land, besides employment being given on it to several labourers. All this has been accomplished by draining the moss with drains at 18 feet apart, 27 acres of which were drained at 9 feet apart; and in order to carry this sort of experiment still further, 1 acre was drained with drains placed only 4½ feet apart, for the crop of Potatoes, on which this season Mr. Cavaniss was offered 20*l.*, but refused it, as he considered the yield to be 50 bolls, the value of which is six times that of the original fee-simple of the ground. His experiments consisted in raising Potatoes on the drained moss with various substances, such as sand, bone-dust, ammoniacal salts, a mixture of bone-dust, ammoniacal salts, and foreign guano, guano and farm-yard dung; the artificial manures cost 5*l.*, and the farm-yard dung 10*l.*, per acre. Of the extraneous substances, the sand yielded the lowest degree of produce, 8 bolls; the guano the highest, namely, 38 bolls, or 7 tons 16 cwt.; while the farm-yard manure yielded 41 bolls, or 8 tons 8 cwt. per acre. Another set of experiments with Potatoes, the manures of which cost 3*l.*, and the farm-yard dung 6*l.* per acre, gave the lowest result on furrow-drained land, inclining to moss, with bone-dust, at 11 bolls, or 2 tons 6 cwt. per acre; and the highest, with farm-dung, 21 bolls, or 4 tons 7 cwt. per acre; but Potatoes planted in the same field ten days earlier yielded with farm-dung 37 bolls, or 7 tons 12 cwt. per acre. The results of experiments in Turnips with the same class of manures gave the lowest return from gypsum, which was 7 tons; and the greatest from farm-yard dung, or 27 tons per acre. The experiments of Mr. Makins were made on Turnips in 1843, on soft, light, hazel-coloured soil, resting on a sandy subsoil, and succeeding a crop of Oats after two years' old lea. The manures employed were guano and farm-yard dung, guano and bones, guano, oil-cake refuse, bones, bones and farm-yard dung, and farm-yard dung. The greatest result, viz., 23 tons 14 cwt., was obtained from guano, at a cost of 3*l.* 18*s.* 1½*d.*, yielding a profit of 3*l.* 4*s.*, 1*d.* per acre, at 6*s.* per ton. The lowest result was given by the farm-yard dung, which, at a cost of 5*l.* 11*s.*, yielded 20 tons, and left a profit of only 9*s.* per acre. The announcement of books and other donations presented to the Society was postponed till next meeting.

Reviews.

Remarks on Lancashire Farming.
By Law. Rawstone, Esq. Longman & Co.

Mr. Rawstone gives a gloomy account of the state of Agriculture in Lancashire.

"The Corn crops look scanty, backward, and half-starved; the grass-land, much of it, as it were, totally abandoned. The whole country seems as if it was running wild with neglect and impoverishment; all attempts at neatness disregarded; no sign of the higher order of cultivation being anywhere visible."

There cannot have been much improvement in a district of which this account is true, since the day when Mr. Dickson reported its condition to the Board of Agriculture in 1815.

This little book, though addressed especially to Lancashire farmers, is capable of being made useful by any of its Agricultural readers.

"The inferiority of Lancashire farming to that of most other parts of the kingdom has not been here dwelt upon for the purpose of raising an invidious comparison, nor of depreciating efforts already laudably made; but rather to spur the country on to a higher range of generous rivalship."

And in order to attain this object, Mr. Rawstone has not only shown up his county, by contrasting it, perhaps too vividly, with other districts; but he states the causes to which the inferiority of its Agriculture is owing, and the methods by which these causes may be removed. All this is exclusively for his neighbours, but the general statement, with which he begins his work, of what it is which constitutes good farming, and the details connected with methods of drainage, and various other branches of cultivation, which he gives us in the course of it, may be made useful by all.

Miscellaneous.

Depth at which Seed should be Planted.—Various experiments have been tried to determine the proper depth at which seeds should be planted. The following result is given by Burger, vol. i., p. 296, with respect to Maize, or Indian Corn:—That which was planted at the depth of

No. 1.	1 inch,	came up in	8½	days.
2.	1½	"	9½	"
3.	2	"	10	
4.	2½	"	11½	
5.	3	"	12	
6.	3½	"	13	
7.	4	"	13½	
8.	4½	"	—	
9.	5	"	—	
10.	5½	"	17½	
11.	6	"	—	

The Nos. 8, 9, 11, were dug up after 22 days, and it was found that No. 6 had an inch more to grow to reach the surface of the earth. Nos. 9 and 11 had just sprouted, but were short, and were three inches below the surface. No. 10 came up in 17½ days, but the tender leaf remained only six days green, and then withered. There is no experiment which shows more clearly the advantage of a shallow planting in a soil not too loose and trodden down like this. The more shallow the seed was covered by the earth, the more rapidly the sprout made its appearance, and the stronger afterwards was the stalk. The deeper the seed lay, the longer it remained before it came to the surface. Four inches was too deep for the Maize, and must also be so for yet smaller grain kernels. It, indeed, came up at that depth, but on the 15th day after it was planted, the experiment being made in the hot time of the year, in June; in the colder season of spring it would have been 18 or 20 days. If the germ-leaves of the seed lie too long under ground they begin to get twisted, and will be bleached and die, as in No. 10, or form weak plants, as in Nos. 7 and 11. Petri cites an experiment made with respect to Rye, in Oct. 1817, with the following results:—

Depth of Seed.	Appeared above ground in	Number of Plants that came up.
½ inch,	11 days,	7-8th
1 "	12 "	all
2 inches,	18 "	7-8th
3 "	20 "	6-8th
4 "	21 "	4 8th
5 "	22 "	3 8th
6 "	23 "	1-8th

The root stalk always forms itself next below the surface of the ground, and if we place the grain deep it must first put out its sprouts to the surface, and form its side-branches in a nearer connexion with the air. We never find that the sucker-roots are ranged from below to above, but the contrary. As a proof of the correctness of this opinion, I will here give the interesting experiment of Ugazy in Andre, Okon, Neuigkeiten (Economical Novelties), July, 1817. He tried 76, between the 5th and 15th of June, 1817, on good soil, where the seed was well ploughed in, with different grains, to ascertain how deep the root-stalk stood in the earth, and what influence the different depths would have on the formation of the stalk. The results are exhibited in the following Table:—

	Number of root-stalks which remained in the earth.				
Name of the kinds of Grain.	At 1 inch.	At 1 to 1 1-2 inches.	At 2 inches.	At 2 to 2 1-2 inch.	Total.
Winter Rye	742	231	32	5	1000
" Wheat	765	215	17	—	—
Summer "	645	304	42	9	—
" Barley	631	317	41	11	—
" Oats	672	241	64	23	—

	Average No. of stalks to a plant.			
Name of the kinds of Grain.	Of the 1st depth.	Of the 2d depth.	Of the 3d depth.	Of the 4th depth.
Winter Rye	2 3-5th	2 1-7th	1	1
" Wheat	3 4-7th	2 1-8th	1	—
Summer "	4 1-6th	2 3-5th	1 1-twelfth	1
" Barley	2 2-5th	1 3-4th	1	1
" Oats	1 1-half	1	1	1

We see here that ¾ to ⅘ of all the plants had their root-stalk only one inch under ground, and that it was just these which produced the most stalks; ⅕ of them had their roots only 1½ inches deep, and only half as many stalks as the first; at two inches deep there were only four in 100, and at 2½ inches deep only nine of 1000, producing only one stalk a-piece, while the first, in Rye and Wheat, produced 2⅗ to 4⅕ stalks. From this it is clear that shallow sowing, if the seed is only so far covered as to sprout, and the germ is protected from immediate contact with the air, is preferable to laying the seed deep, because it springs up quicker, and acquires a stronger growth, and has hardier plants.—*Note to Burger's Economy of Farming.*

Rearing Cattle, with a view to Early Maturity.—The production of beef at the quickest and cheapest rate being the object in view, the first requisite is a stock of cows possessing qualities suitable for this purpose. Accordingly, they should be good milkers—able to keep at the rate of two and a half to three calves each—of a kind known to have a tendency to fatten readily, and to come early to maturity, and of a structure likely to produce a vigorous well grown steer. In other words, they must be good short-horns; only having more regard to their milking properties than is usually done by breeders of bulls. And here it may be well to notice, that it is in general highly inexpedient for the beef grower—the farmer who depends largely on his regular cast of fat cattle—to attempt breeding his own bull. It is only a few individuals in any district who have the taste and skill requisite for this difficult department of the business, not to mention the large capital which must necessarily be invested in it, the precariousness of the return, the greater liability to casualties of such high-bred animals, and the additional expense of their housing and maintenance. On Tweed side, the breeding of bulls is confined to a very limited number of persons, chiefly Northumbrians, who, by devoting their whole attention to this department, are able, from year to year, to furnish a class of bulls which are steadily improving the general breed of the district. The contrary practice is at this moment compromising the character of this valuable breed of cattle in several districts of Scotland into which they have been more recently introduced. Made wiser on this point by experience, the farmer of the Border purchases from some breeder of established reputation a good yearling bull, which he uses for two or three seasons, and then replaces by another in like manner. This bull serves his own cows and those of his hinds, and some of the neighbouring villagers; and thus, though his own stud be limited to six or eight cows, he can select from the progeny of his own bull as many calves as he requires to make up his lot, and has them more uniform in colour and quality than could otherwise be the case. As the male parent, among sheep and cattle, is known to exert by far the greatest influence in giving character to the progeny, and increasingly so in proportion to the purity of his breeding, it is evidently much for the advantage of the beef grower to spare no reasonable trouble and expense in obtaining a bull of thorough purity, and then to select his calves with the most scrupulous attention. From overlooking all this, how often may lots of cattle be seen, on the best of land, too, which can only be fattened at an enormous expense of food and time, and, after all, are so coarse in quality as to realize an inferior price per stone. Occasionally a few beasts of the right sort will be seen in such lots, which, by going ahead of their fellows, to the extent of 4*l.* or 5*l.* a-piece of actual market value, show what might have been done by greater skill or attention on the part of the owner. It is very desirable to have all the cows to calve betwixt 1st February and 1st April. If earlier, they will get almost dry ere the grass comes, and calves later than this will scarcely be fit for sale with the rest of the lot. When a calf is dropt, it is immediately removed from its dam, rubbed dry, with a coarse cloth or wisp of straw, (this being what the cow would do for it with her tongue, if allowed,) and then placed in a crib in the calf-house among dry straw, when it receives a portion of its own mother's first milk, which, being of a purgative quality, is just what is needed by the young animal. For a fortnight, new milk is the only food suitable for it, and of this it should receive a liberal allowance thrice a day; this means should now be used to train it to eat linseed cake and sliced Swedish Turnip; and the readiest way of doing so is to put a bit of cake into its mouth immediately after getting its milk, as it will then suck greedily at anything it can get hold of. By repeating this a few times, and placing a few pieces in its trough, it will usually take to this food freely, and, whenever this is the case, it should have as much as it can eat, that its allowance of milk may be diminished, to meet the necessities of the younger calves which are coming in succession. This is of the greater importance that it is always most desirable to avoid mixing anything with their milk by way of helping the quantity. When a substitute must be resorted to, oatmeal porridge mixed with the new milk is perhaps the best. Sago has of late years been much used for this purpose; but an eminent English veterinary surgeon has recently expressed a very decided opinion that its use impairs the digestive powers of the animal, and predisposes to disease. The sour smell invariably found in a calf-house, where porridge or jelly of any kind is mixed with the milk, is proof sufficient that indigestion is the consequence. An egg put into each calf's allowance, and mixed with the milk by stirring with the hand, is a good help, and never does harm; but, with this exception, it is best to give the milk warm and unadulterated, however small the quantity, and along with this, dry farinaceous food, turnips and hay, *ad libitum*. If more liquid is needed, a pail with water may be put within their reach, as this does not produce the bad effects of mixed milk. Indeed, in this, it is best to keep as closely as possible to the natural arrangement according to which the calf takes its suck—at first frequently, and then at longer intervals as it becomes able to eat of the same food as its dam. The diet of the cows at this season is a matter of great consequence. Swedish Turnips yield the richest milk, but it is too scanty, and calves fed on it are liable to inflammatory attacks. Globe Turnips should, therefore, form their principal food during the spring months. Care must also be taken that they do not get too low in condition in the autumn and winter, and for this end it is well to put them dry at least three months before calving. Some may think this long; but, on a breeding farm, milk is of little value at this season. The cows, when dry, are kept at less expense, and, by this period of rest, their constitution is invigorated, greater justice done to the fœtus, now rapidly advancing to maturity, and so much more milk obtained after calving, when it is really valuable. When the calves are from four to six weeks old, they are removed from their separate cribs to a house where several can be accommodated together, and have room to frisk about. So soon as the feeding-yards are cleared of the fat cattle, the calves are put into the most sheltered one, where they have still more room, and are gradually prepared for being turned to grass; and, when this is done, they are still brought in at night for some time. At six weeks old, the mid-day allowance of milk is discontinued, and at about 14 weeks they are weaned altogether. When this is done, their allowance of linseed cake is increased; and, as they have been trained to its use, they readily eat enough to improve in condition at this crisis, instead of having their growth checked, and acquiring the large belly and unthrifty appearance which used to be considered an unavoidable consequence of weaning. The cake is continued until they have so evidently taken with the grass as to be able to dispense with it. They are not allowed to lie out very late in autumn, but, as the nights begin to lengthen and get chilly, are brought in during the night, and receive a fodderings of tares or clover fogagge. When put on Turnips, the daily allowance of cake (say 1 lb. each) is resumed, and continued steadily through the winter and spring, until they are again turned to grass. This not merely promotes their growth and feeding, but (so far as the experience of five or six years can determine the point) seems a specific against black-leg, which was often so fatal as altogether to deter many farmers from breeding. It may be well to state here distinctly the particular purpose for which cake is given at the different stages of their growth. At first, the object is to accustom them to a wholesome and nutritious diet, which will supplement the milk obtained from any given number of cows, so as to admit of a greater number of calves being reared, and, at the same time, have greater justice done them than could otherwise be practicable. At weaning-time, again, it is given to help the young animal over the transition from milk to Grass alone, without check to growth or loss of condition. During the follow

NEW FARMERS' NEWSPAPER.

The time has come when Landlords and Tenants, large Farmers and small, must devote their [illegible] attention to [illegible] question—when, in the words of Sir Robert Peel, 'All must learn how, in the [illegible] time, and at the least expense, to produce the greatest quantity of food, consistently with [illegible] future to the land.' To accomplish this, no means can be so [illegible] as that which brings the results of Experiments and Science before every man, in a [illegible] for this purpose THE AGRICULTURAL GAZETTE is established.

The Proprietors are aware of the difficulties of dealing with the many details of cultivation, [illegible] in connexion with climate, soil, and [illegible] as varying as places. They condemn the idea of conducting farming operations upon one [illegible] plan; and, while they welcome science in its [illegible] of principle, they [illegible] crude speculations as the most dangerous of delusions. Still, they also feel that in Agriculture, as in all other arts, there are general principles upon which [illegible] must depend, and [illegible] are practical errors which no local circumstances can justify; in short, that there is room for improvement even in those branches which are best understood. To this [illegible] upon the multifarious questions affecting husbandry, and the duty of the Editor of such a Paper as THE AGRICULTURAL GAZETTE is to make known the knowledge of all. [illegible] Farmers that the Proprietors trust for the means of carrying out their views, and not to the talents of any individual. While, therefore, they state that the Editor of THE AGRICULTURAL GAZETTE is a gentleman well acquainted with the best kind of farming, in which he is actively engaged, they feel it to be of far more importance to announce the promise of assistance [illegible] with the landed and farming interest generally, especially of those whose names they are permitted to mention—

The Right Hon. the Earl Spencer, President of the Royal Agricultural Society of England.

The Right Hon the Earl of Ducie, Vice President of the Royal Agricultural Society of England
Sir Charles Lemon, Bart, M.P., one of the Council of the Royal Agricultural Society of England

&c. &c. &c.

The Practice of Agriculture—its Science—Animal and Vegetable Physiology—Improvements in Implements—better modes of Husbandry—results of well conducted experimental Farming—Growth and Rotation of Crops—Stock—Drainage—Irrigation—Foresting—Road making—Farm-Buildings—Labourers—in short, whatever affects the beneficial employment of capital in land—will form topics of consideration Reports will be given of the English, Scotch, and Irish Agricultural Societies—London Market Prices of Corn, Hay, and Cattle, and the Weekly Averages. Replies to questions connected with the object of the Paper will also be furnished weekly

Considering the union which exists between Horticulture and Agriculture, it has been thought advisable to make THE AGRICULTURAL GAZETTE an addition to the GARDENERS' CHRONICLE, edited by DR LINDLEY, and so extensively known; but that there may be ample room for discussion, that Paper *has been increased one-half in size without additional charge*—thus Twenty-four Columns will be occupied, as at present, by Horticulture, and Twenty-four by the General News of the Week, whilst

Twenty-four Columns will be devoted to Agriculture:

This day, therefore, January 13th, is published, price SIXPENCE, stamped to go free by post, the SECOND NUMBER *of*

THE GARDENERS' CHRONICLE
AND
AGRICULTURAL GAZETTE:

A Weekly Record of Rural Economy and General News.

THE HORTICULTURAL PART EDITED BY PROFESSOR LINDLEY.

THE principle on which the Gardening part of this Paper is conducted is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects Connected with this part are WEEKLY CALENDARS OF GARDENING OPERATIONS, given in detail, and adapted to the objects of persons in every station of life, so that the Cottager with a few rods of ground before his door, the Amateur who has only greenhouse, and the Manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It moreover contains reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in short, everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer, accompanied with Woodcuts, whenever the matter treated of requires that mode of illustration.

To this Farming, as explained above, is now added.

Lastly, that description of domestic and political News is introduced which is usually found in a Weekly Newspaper It is unnecessary to dwell on this head further than to say, that the Proprietors do not range themselves under the banners of any party, their earnest endeavours are to make THE GARDENERS' CHRONICLE a full and comprehensive *Record of Facts* only—a NEWSPAPER in the true sense of the word—leaving the reader to form his own opinions; their object being elucidation of the laws of Nature, not of man. The reader is thus furnished, IN ADDITION TO THE PECULIAR FEATURES OF THE JOURNAL, with such information concerning the events of the day as supersedes the necessity of his providing himself with any other Weekly Paper.

The Proprietors are happy to announce that the following distinguished Botanists, Florists, and Practical Gardeners have already enriched the GARDENERS' CHRONICLE by their communications:—

The Hon. and Very Rev W Herbert, Dean of Manchester
The Hon and Rev Charles Bathurst
Hon. W Fox Strangways
Sir Oswald Mosley, Bart.
Sir W J. Hooker, Royal Gardens, Kew
Dr. Horner, Hull
Dr. Lancaster, F L.S
Dr. Mall, Canon Mills
Rev. J. M Berkeley
Capt Widdrington
Professor Morren, Liege
J. Bateman, Esq, Kingersley
C Barker, Esq, Birmingham
E. Barnard, Esq, F R S
Mr. W Billington, Oswestry
Mr. Mc Nab, Caledonian Society's Garden
Mr Meehan, Botanic and Zoological Gardens, Leeds
Mr Ingram, Gardener to Her Majesty
Mr. Paxton, Gardener to the Duke of Devonshire
Mr. Alexander, Gardener to the Duke of Leinster
Mr. Ferguson, Gardener to the Duke of Buckingham
Mr. Spencer, Gardener to the Marquis of Lansdowne
Mr. Elliott, Gardener to the Earl of Tyrconnell

Hon. Algernon Herbert
Sir George Mackenzie, Bart.
Sir Charles Wolseley, Bart
Captain Churchill, R M.
Dr. Bevan, Llanferry
Dr Gregory, Aberdeen
Dr Ingram, President of Trinity College, Oxford
Dr Wilson, Truro
Rev J B Reade
Professor Royle
Professor Graham
G Wailes, Esq, Secretary of the Hort. Soc, Newcastle
Mr Appleby, Gardener to T Brocklehurst, Esq., M.P.
Mr Marnock, Royal Botanic Society, London
Mr Cameron, Royal Botanic Gardens, Birmingham
Mr Henderson, Gardener to the Earl Fitzwilliam
Mr Frost, Gardener to Lady Grenville
Mr. Haythorn, Gardener to Lord Middleton
Mr Halliday, late Gardener to Lord Dundas
Mr Brown, Gardener to Lord Southampton
Mr Errington, Gardener to Sir P. Egerton, Bart.
Mr Fortune, Hothouse, Dept., Hort Gardens, Chiswick
Mr Thompson, Fruit Dept., Hort. Gardens, Chiswick

Sir James Nasmyth, Bart.
Sir James Macadam
Dr Hamilton, Plymouth
G Bentham, Esq., late Secretary of the Horticultural Society
L. W. Dillwyn, Esq., Sketty Hall
J D Llewelyn, Esq, Penllergare
Mr Campbell, Botanic Garden, Manchester
Mr Williamson, Botanic Garden, Sheffield
Mr. Bailey, Gardener to the Archbishop of York
Mr. Mackintosh, Gardener to the Duke of Buccleuch
Mr Moffat, Gardener to the Duke of Newcastle
Mr. Tilley, Gardener to the Duke of Portland
Mr Cooper, Gardener to the Earl Fitzwilliam
Mr. Bowers, Gardener to the Earl of Leven
Mr Forsyth, Gardener to the Earl of Shrewsbury
Mr Buchan, Gardener to Lord Egerton
Mr Beaton, Gardener to Sir W. Middleton, Bart.
Mr Booth, Gardener to Sir C Lemon, Bart.
Mr. Whiting, Gardener to R. T. Hope, Esq., M.P.
Mr. James Drummond, Gardener, Blair Drummond
Mr Gordon, Hardy Dept., Horticultural Gardens, Chiswick.
Mr W. P Ayres, Brooklands
Mr. Wells, Gardener to W. Wells, Esq., Redleaf

GARDENERS' BENEVOLENT INSTITUTION.

—At a special General Meeting of the Subscribers to this Institution, held on THURSDAY, Jan. 11, at the Crown and Anchor Tavern, for the special purpose of Electing Two poor persons on the Pension List of this Charity, the following was the result of the Ballot, viz. —

James Anderson	aged 73		174 votes.
Ann Potter		68	140
Elizabeth Collyer		69	30
Samuel Lywood		66	22
John Blaylock		71	16

The Meeting then declared that James Anderson and Ann Potter, having the greatest number of votes, were duly elected Pensioners of this Charity.

Edw. R. Cutler, Sec

TO THE SUBSCRIBERS OF THE GARDENERS' BENEVOLENT INSTITUTION.

ANN POTTER begs to return her grateful thanks to those Friends and Subscribers who so kindly exerted themselves on her behalf on Thursday, January 11th last, and by whose means she has been placed on the list of Pensioners.—Coombe-lane, Kingston, Surrey, January 15th, 1844

GARDENERS' CHRONICLE for Sale.—The first 3 volumes clean and in good condition; volumes 1 and 2 in boards, 2 published. Price 3 guineas.—Apply to Mr. Loadman, Stationer, Kingston New Town

THE LATE Mr. LOUDON.—A Public Meeting of the Friends of the late Mr. Loudon will be held in the large room of the Horticultural Society's Establishment, Regent-street, London, early in February next, to consider the best means of extricating his Widow and Daughter from the difficulties into which they are placed by Mr Loudon's sudden death.

Due notice will be given of the day of meeting, when it is hoped that Gentlemen and gentlemen who patronise Horticulture, and most of Gentlemen and Nurserymen who are within a reasonable distance, will attend.

AT a MEETING of the LINCOLN and LINDSEY AGRICULTURAL ASSOCIATION, held at the City Arms Hotel, Lincoln, on the 8th day of January, 1844, C Chaplin, Esq., in the Chair, The following Resolutions were adopted —

1. That while the tenantry of the country, and others investing their capital in Agriculture, have had their protection greatly reduced by recent Legislative enactments, it is the opinion of this Society that it would be the height of absurdity to countenance any scheme, however plausible, which in effect will tend still more to depreciate the productions of our soil, and thereby spread inevitable ruin throughout the rural districts of the country.

2. We, therefore, desire to reiterate our unalterable conviction that a repeal of the Corn Laws would be highly prejudicial to British Agriculture, and to the nation at large, and that the efforts of the Anti-Corn Law League to bring about this object ought to be vigorously resisted.

3 That the doctrines taught by the emissaries of the League, tending to produce alienation and distrust between landlord and tenant, between the employer and the labourer, are un-Christian, anti-social, and dangerous to the peace of the country; and we the Members of this Association, pledge ourselves to oppose such principles to the utmost of our power, and to this good end we allude for the co-operation of all societies established in this county for a similar object.

4. That a Committee be now appointed to correspond with the other societies in this county formed for a similar purpose, and to adopt such measures as to them shall seem expedient.

5 Resolved.—That a subscription in aid of the object of the Contingent Fund of this County be now entered into, and that the Secretary be requested to write to the principal landed proprietors, requesting their patronage in aid of the same.

6. Resolved.—That these resolutions be published.

(Signed) Charles Chaplin, Chairman.

Resolved.—That the cordial thanks of this meeting be given to the Chairman.

The following Subscriptions have already been received.—

TO GENTLEMEN PLANTING.

MESSRS J. FAIRBAIRN are induced from the unusually mild weather which they hold the Management Nursery, Clapton, peculiarly conducive to the Home Nurseries, Clapham Rise, to offer (with the exception will be given to all applications), to select a Sale of the Stock at as early a period as possible, consequently beg to solicit the attention of Gentlemen and the trade to the large and remarkably healthy gardeners-grown stock, consisting of fine large Laurels, twice transplanted, of strong growth; Portugal Laurels, very handsome; Queen Hollies, of various sizes; Evergreen Privets, fine Standard and Dwarf Roses in great variety; fine standard flowering Thorns, Almonds, Laburnums, Deutzias, and other Ornamental Trees, and Evergreen and flowering shrubs, with a large stock of fine standard and dwarf, trained and unnamed Peaches, Nectarines, Apples, Pears, Plums, and Cherries, of the most approved kinds, and of growth rarely equalled, also, a large assortment of Forest Trees consisting of Limes, Elms, Ashes, Beech, Hornbeam, Spanish and Horse Chestnuts, Mountain Ash, Poplars, and Larches, and Scotch Firs, also a large number of Rhododendrons and Cupressus, of excellent growth and of the finest varieties in cultivation, to all of which J. & J. F. respectfully invites the inspection of Gentlemen and Nurserymen, flattering themselves that the general character of the Stock is such as to afford unqualified satisfaction, and which they are disposed to dispose of very moderate prices for cash

J. & J. F. respectfully beg to call the attention of Gentlemen to their advertisement of Heaths, &c., which has lately appeared in the *Gardeners' Chronicle* (Oct. 21 and 28)

Nurseries, Clapham, near London Jan. 5, 1844

SPLENDID NEW SEEDLING CINERARIAS.—Fine early flowering strong plants of CINERARIAS, saved from the very choicest sorts of large and crimson colours, selected from between five and six thousand Seedlings of last year. Those purchasing will have an opportunity of flowering some of the choicest sorts in cultivation, remarkably healthy, and having a large stock they can be sold at 2s. and 12s. per dozen, carefully packed for any part of the country. Applications including Post-office orders will be immediately executed. Large bunches of RUSSIAN VIOLETS in full flower, 2s. per package, 6s. and 9s. per dozen.—Direct to MICHAEL BARRON, Seed Cambridge Nurseries.

T. & C. LOCKHART & DUNCAN, SEEDSMEN AND Florists, 155, Cheapside, London, have just published their List of Seeds and Ornamental Greenhouse and Hardy Plants, which they will forward, free by Post, on application. They have purchased some very superior Pink Seed of one of the first growers, which they are selling in packets at 2s. 6d. and 5s. each. As it rarely occurs that it is offered of such quality, and as the Stock is very limited, they respectfully request early orders. Shown in March, Pink Seed flowers the same season. Early Wallflowers Brocatti Seed, 4s. per ounce, sent free by Post.

JOSEPH HAMILTON'S unparalleled successful system of cultivating the FIVE APPLES and CUCUMBER, together with Hints on the VINE, has been long delayed by the printer (will be ready on the 25th inst., positive). Price 6s. London: published by Mr JOSEPH MARSHALL 33, Aldersgate-street, and sold by all other Booksellers; also of Mr THOMAS WILDS, Bookseller, Ipswich, or of the AUTHOR, Thornfield, near Stockport, Lancashire.

MANNOCK AND MANLEY'S CATALOGUE of NEW AND CHOICE FLOWER-SEEDS, with full and particular Directions for the best Modes of Cultivation, with the Varieties on the Waleheren Cauliflower is now ready, and may be had on application.

THE Stock of trained Fruit trees are exceedingly fine, consisting of all the leading varieties of Peaches, Nectarines, Apricots, Plums, &c. Also the following Cherries:—Harrison's Black Heart, Adam's Crown, Waterloo, Knight's Early Florence, Black Eagle, Downton, Late Duke, May Duke, Kentish, Elton Napoleon, Early Purple, Circassian, Kentish, Morello of sorts, &c. Prices may be had on application at their Nursery, Hackney, London.—Jan 17, 1844

EARLY PEAS, &c.—HENRY D. CORMACK, Horticulturist, &c., begs to inform the readers of the *Gardeners' Chronicle* that they can be supplied with the following Early and Prolific Varieties, viz Cormack's Prince Albert, British Queen, and Early Kent Peas; Taylor's Improved Windsor, Mills' Johnson's Wonderful Bean; Manchester Red and Seymour's White Celery, Walker's Long and Hamilton's Cucumber, &c., with every other variety of Horticultural and Agricultural Seeds, at his Wholesale and Retail Seed Warehouse, 166, Deansgate, Manchester

THE BRITISH QUEEN AND PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above two new varieties, the merits of which are thus noticed in the *Gardeners' Chronicle*: "THE BRITISH QUEEN on light soils, is the best of all kinds and will drive Knight's Tall Marrow out of the garden." "THE PRINCE ALBERT, which has been cultivated in the Garden of the Horticultural Society during the season, produced Peas fit for the table *ten days earlier* than any other variety sown at the same time." Both varieties may be had in packages at 2s. 6d. each, at W. J. C.'s wholesale Establishment, New Cross, or the Bedford Conservatory, Covent Garden

SHILLING'S EARLY GROTTO PEA

JAMES S. SHILLING have succeeded in raising the above PEA, the Early Frame Pea, impregnated with the flavour of Oyster Marrow, which they, with confidence, recommend to the Public generally, being quite as early and nearly double the size of any other Pea in cultivation. Quite hardy, will stand the winter well, and a good bearer: the pod large and long. They would particularly recommend it to the attention of Market Gardeners. Price 3s. per quart; 10s. per gallon, 17s. 6d. per peck; 35s. per half-bushel; 70s. per bushel. Agents—Messrs. Parry and Lucas, 139 Lower Thames-street, London; Messrs. W. and J. Noble, 154, Fleet street; Mr HANNAH, 4, Great Russell-street, Covent Garden; Messrs. Hugby and Hobbs, 61, Leadenhall-street; Messrs. GRAY, ADAMS, and Sons, Kensington.—Northamptonborough Nursery, near Odiham, Hants, Jan. 4, 1844

HOGNAMES MELON SEED

R. WHITE & Co beg to inform their Friends and the Public, that their new Culinary and Flower seeds are now ready for delivery, and include a few remaining packets of their above splendid variety of Melon, from the fruit exhibited by Mr. Fleming, at 5s. per packet. Also, true Waleheren Cauliflower Broccoli, at 2s. per oz. A new and very fine Vegetable Marrow, noticed by Dr Lindley as being superior to all others; together with every other truly desirable kind. Kitchen-garden Seeds in collections of all the best kinds, in quantities from a one-rate establishment, sent free to all parts, 21s. &c. The same in smaller quantity, at 2s. Complete collection suitable for another families, 11. 1s. A fine Collection of Flower Seeds, containing 50 distinct and choice kinds, 11. 1s. Orders from unknown correspondents must contain remittance.

Poole Nursery, Jan. 12, 1844.

TO FLORISTS, NURSERYMEN, &c.

AUSTIN & SEELEY have now a Quantity of GARDEN ORNAMENTS, which have been discovered by exposure to the London atmosphere, that which they are therefore desirous of selling at a considerable reduction.—New Road, Regent's Park.

DOUBLE ITALIAN TUBEROSE ROOTS.

THE ANNUAL IMPORTATION of these fine FLOWER-ROOTS has just been received by PAMPARINI VALLE, at his old Italian Warehouse, 38, Haymarket.

TO SEEDSMEN AND OTHERS.

FOR ABSOLUTE SALE (in order to clear the stock), in one or more Lots, a Quantity of SEEDS, consisting of Cabbage Coul flower, Broccoli, Radish, Scorzonera, Celery, Cucumber, Best Native, Purple, the Newest Potato, &c. &c. &c.

For particulars apply to Messrs. Thompson & Morris, American Nursery, Leytonstone, N.E. A Discount of 5 per cent. will be allowed to all purchasers above 10*l*

HORTICULTURAL IMPROVEMENT

READ'S PATENT GARDEN SYRINGE, for the invention of which he has been honoured with the Silver Medal of the Royal Horticultural Society, as the best instrument ever offered to their notice. J. R. has so improved the above, by an additional branch, to turn in every direction, so that water may be dispensed into a l pots in Conservatories, in a perpendicular direction, resembling a gentle shower or dowfall, and in any quantity, from a pint to a table spoonful. Likewise, small Machines, Pails, Trucks, and Garden Engines of every description, that will discharge water in a continuous, powerful stream, made on the most improved principle, and may be worked with half the usual labour required for other Engines now in use. The above are the best adapted for destroying insects, which make such deadly havoc on all choice Fruit-trees and Plants in Gardens, &c. which the Patentee, from 21 years' experience in Gardening, and 23 years in Manufacturing and Improving Instruments, can safely warrant. His valves, being solid metal, can never get out of repair. May be seen and proved at the Patentee's, 24, Regent Circus, Piccadilly. N.B.—None are genuine except stamped with the words, "READ'S PATENT."

HORTICULTURAL SOCIETY OF LONDON.—LIST OF PRIZES

OFFERED AT THE EXHIBITIONS IN THE GARDENS, IN 1844.

MEDALS AND REWARDS

The Society distributes the following Medals and Rewards, viz

	value—£	s	d
C The Certificate	0	10	0
SB Silver Banksian Medal	1	0	0
SK Silver Knightian Do.	1	5	0
LS Large Silver Do.	1	15	0
SG Large Silver Gilt Do.	4	0	0
GB Gold Banksian Do	7	0	0
GK Gold Knightian Do	10	0	0
LG Large Gold Do.	20	0	0

Exhibitors to whom any of these shall be awarded can exchange them one for another, or may receive their value in money, or in plate. In case an Exhibitor shall receive a First Prize in any one Letter, he shall not be entitled to receive any other Medal in the same Letter, except in *CC*, *DD*, and *EE*

CLASS I.—FLOWERS; for which Nurserymen and Private Growers exhibit independently of each other.

A. Pelargoniums, in collections of 12 new and first rate varieties, cultivated with superior skill, in pots of 24 to a mast. GB—SG—LS—SK.

B Pelargoniums, in collections of 12 varieties, in pots of 12 to a cast. SG—LS—SK

N B. Persons exhibiting in *B* cannot also exhibit in *C*

C Pelargoniums in collections of 6 varieties, in pots of 6 to a cast. LS—SB

D Rhododendrons in pots, not fewer than 6 plants, in 6 varieties. LS—SK—SB

E Roses, in pots; Amateurs to show in collections of 12, Nurserymen in collections of 25, distinct varieties. GB—SG—LS

N B It is the wish of the Society in a future season, to require Roses to be shown exclusively in pots, and not to allow cut specimens to be exhibited at all

F Moss Roses in loose bunches, so as to exhibit, as far as possible the habit of the variety; in 12 varieties. SK—SB—C

G Other Roses exhibited as in the last letter, and in 50 varieties. LS—SK—SB—C.

N B No one who exhibits in this letter can also compete for the following

H Other Roses, exhibited as in the letter *F*, and in 25 varieties. SK—SB—C

N B Highly medals than those here offered for Roses cannot be given by the Judges. And if Roses are brought for exhibition without attention to the regulations here explained, they will not be allowed to be placed on the tables.

I Cape Heaths, in collections of 20 distinct varieties. GB—SG—LS

N.B It is expected that the same plant shall not be exhibited on more than one occasion.

K Cape Heaths, in collections of 6 distinct varieties. SG—LS—SK.

N B No person who shows in *I* will be allowed to exhibit also in *K*.

L Calceolarias, in sixes; in pots of 12 to the cast. LS—SK—SB.

M. Cinerarias, in pans of 24 distinct varieties. LS—SK—SB.

N Pelargoniums, in pans of 24 distinct varieties. LS—SK—SB

O. Pinks, in pans of 24 distinct varieties. SK—SB

CLASS II.—FLOWERS; for which all persons are admitted to equal competition.

P Stove or Greenhouse Plants, in collections of 30 plants. GK—GB—SG—LS.

N.B Heaths, Calceolarias, Fuchsias, Greenhouse Azaleas, Rhododendrons, Orchidaceæ, Cacti, and Pelargoniums, to be excluded from *P*, *Q*, and *R*

Q Stove or Greenhouse plants, in collections of 15 plants. GB—SG—LS

N.B. Persons exhibiting in *P* not to compete in *Q* also

R. Stove or Greenhouse plants, in collections of 6 distinct species. SG—LS—SK.

N B Persons exhibiting in *P* or *Q* will not be allowed to compete in *R* also.

S. Greenhouse Azaleas, in 12 distinct varieties. GB—SG—LS.

T. Greenhouse Azaleas, in 6 distinct varieties. SG—LS.

N B. No one can show in both classes of Azaleas.

U. Stove or Greenhouse climbers, in collections of 6 species. SG—SK.

V Exotic Orchidaceæ, in collections of not fewer than 20 species. LG—GK—GB

N B Exhibitors cannot show in more than one of the classes I, H and K.

W Exotic Orchidaceæ, in collections of not fewer than 6 species. (GK—GB—SG)

X Exotic Orchidaceæ in single specimens. SG—LS—SK.

Y. Plants in glass cases, grown on Mr. Ward's plan. SG—LS—SK

N.B It is highly desirable that these cases be made with a movable door, so as to prevent the condensation of the water on the inner tops of the glass during the time of exhibition

Z. Distinct varieties of Tall Cacti in flower. GB—SG—LS.

N.B. The GB and SG Medals are not to be given if fewer than six varieties are exhibited.

AA. Fuchsias in collections of 12 distinct varieties. LS—SK.

BB. Cinerarias, in pots, in collections of 12 distinct varieties. LS—SK.

CC. Single specimens of such as extremely rare or remarkable species. LS—SK—SB.

N.B. These Medals will be awarded by the distinct Committees, and not by the usual Judges. Exhibitors will particularly observe that none but new or rare plants can be exhibited under this letter. *Nothing will be considered as such which has been exhibited in the Gardens in a previous season.*

DD. Miscellaneous subjects. SK—SB—C.

N.B. Cockscombs, Heartsease, Hyacinths, and cut flowers, are altogether excluded from this division. Exhibitors under this head will not be thereby entitled to a glass ticket.

EE Bunting Morlds' flowers. SK—SB—C.

N B Every seedling must be shown singly, and must be marked with the name it is to bear. The same seedling cannot gain a prize more than once in the season. Polyanthuses are to be shown in pots, and not in a collection. No person will be allowed to exhibit more than two seedlings at each meeting. Exhibitors under this head will not be thereby entitled to a pass ticket.

IN ADDITION to any medals assigned to the classes *F*, *P*, *Q*, and *W*, the SK and SB medals are offered for the two collections in those classes which shall be best adapted by the Exhibitor

N B The Society's officers, who will make this award, will be guided in their judgment by a consideration not only of the correctness of the names, but of the accuracy of the spelling, and the neatness of the writing.

CLASS III.—FRUIT, for which Market Gardeners, Fruiterers, or persons in the habit of regularly supplying the market, and private growers, exhibit independently of each other.

N B All Fruit must be FULLY ripe and WELL COLOURED; if the contrary it will be disqualified

FF Miscellaneous collections of Fruit, consisting of at least three different kinds, Peaches and Nectarines being considered as only one kind. GK—GB—LS

N B Cucumbers, Tomatoes, Gourds, and similar Kitchen garden products, are excluded from this letter.

GG Grapes. SG—LS—SK—SB

HH Pine-apples. SG—LS—SK—SB.

II Peaches or Nectarines, in dishes of six specimens. SK—SB.

KK Other kinds of Fruit. SK—SB—C.

JUDGES.—The Judges have the power *of increasing or diminishing* the number and value of the silver medals offered by the Society for particular objects, and also *of conferring* Silver Medals or Certificates in cases not contemplated in these regulations, if they think it necessary to do so.

The Judges are also required to bear in mind that the Society's Medals are offered less for new and curious objects, than for fine specimens of Horticultural skill, the design of the Council in instituting these meetings being not so much to encourage the collector as to reward the skilful Gardener; they are also not to make any award in cases where the objects exhibited do not appear worthy of a Medal; others of a bad single exhibition might obtain a prize, merely because there is no better exhibition of the same class to oppose it.

Copies of the above list may be obtained at 21, Regent-street, upon application to the Secretary.

NEW WORKS FOR THE USE OF FARMERS.

This Day is Published, Imperial 8vo., half-bound, 16s.

BRITISH FARMER'S ANNUAL ACCOUNT-BOOK, upon a New and Improved System. By the Author of "British Husbandry."

Also, by the Same Author, in a Small Volume, Fcap 8vo., 2s. 6d.

MUCK MANUAL; for the USE of FARMERS; being a PRACTICAL TREATISE on the NATURE and VALUE of ANIMAL and VEGETABLE MANURES.

"A little volume which, for its valuable information, will be read with avidity."—*Farmer's Herald.*

"Addressed to the practical farmer, and written as such books ought to be."—*Bell's Weekly Messenger.*

"Of great value, and ought to be the pocket companion of every farmer."—*Devonshire Courier*

JOHN MURRAY, Albemarle Street,

Publisher to the Royal Agricultural Society of England.

On January the 8th, 1844, will be published, handsomely printed in Demy 8vo., Part the First, Price 12s.,

SPECIES FILICUM; or a SYNOPSIS OF ALL KNOWN FERNS. This first part contains Cystopteris, Polypodium in part, and Platyloma to it. By Sir WILLIAM JACKSON HOOKER, K.H., LL.D., F.R.S., &c. &c., Vice President of the Linnean Society, and Director of the Royal Botanic Garden at Kew

*** It is intended to publish Part the Second on the 1st March, 1844.

London: WILLIAM PAMPLIN, 45, Fleet-street, corner of Chancery-lane.

HOOD'S MAGAZINE.—The JANUARY Number was published on the Morning of Saturday, 30th Dec., in time for the Booksellers' monthly parcels to all parts of the Kingdom. Subscribers are requested to give EARLY Orders for the Second Number to their respective Booksellers. All complaints of delay or difficulty in the execution of orders are requested to be addressed to the Office, 1, Adam-st., Adelphi.

In Weekly Numbers, price Three Halfpence, and Monthly Parts price Sevenpence,

CHAMBERS' EDINBURGH JOURNAL; a New Series, in an improved form, offering an opportunity for commencing the Work, without the necessity of purchasing the previous volumes.

A Stamped Edition, price Twopence-halfpenny, or sent weekly on payment of a quarter in advance.

W. S. ORR and Co., London. Orders received by all Booksellers and Newsvenders.

NEW BOOKS BY WILLIAM BUTLER.

EDITED BY THOMAS BOURN.

CHRONOLOGICAL, BIOGRAPHICAL, HISTORICAL, and MISCELLANEOUS EXERCISES. 14th Edition. 12mo. 7s. 6d bound

2. ARITHMETICAL QUESTIONS. 13th Edition, with Additions by GEORGE FROST. 12mo. 3s bound.

3. EXERCISES on the GLOBES and MAPS, interspersed with Historical, Biographical, Chronological, Mythological, and Miscellaneous Information. To which are added QUESTIONS FOR EXAMINATION. With an Appendix, by which the Constellations may be easily known. 14th Edition. 12mo., 3s. bound

4. A KEY to the EXERCISES on the GLOBES. 2s 6d sewed.

5 MISCELLANEOUS QUESTIONS in ENGLISH HISTORY and BIOGRAPHY. 8th Edition. 12mo. 4s bound.

6. GEOGRAPHICAL EXERCISES on the NEW TESTAMENT; describing the Principal Places in Judea, and those visited by St. Paul; and containing the most important occurrences recorded in the Evangelical Narrative. With Maps, and a Brief Account of the Principal Religious Sects. 5th Edition. 12mo., 3s. 6d. bound.

7. ARITHMETICAL TABLES, &c. 20th Edition, with Additions. 2d.

Sold by Darton & Harvey, and Simpkin, Marshall, & Co.

THE VALUE OF LANDED PROPERTY, &c.

Just Published, in 8vo., price 12s. cloth boards, the Second Edition, with Additions and Corrections, of

THE VALUE OF LANDED PROPERTY, the Investment of Money, and the Calculation of Compound Interest, Annuities, Assurances, Renewals, Reversions, Freehold Purchases, Copyholds, Leaseholds, Advowsons, Tithes, Rent-charges, Annuities for Lives, Sinking Funds, Renewable Leaseholds, Timber, Dilapidations, Fines, Income Tax, Probate Duty, Succession Duty, Annuities for Terms of Years, Life Assurance, Mortality, Population, Interest, Discount, Exchange, Bullion, Foreign Coins, Annuities, Funds, Shares, Mines, Canals, Railways, Patents, Copyright, Annuities for Lives

HORTICULTURAL SOCIETY OF LONDON.—Notice is hereby given that the Exhibitions of Flowers and Fruit, in the Society's Garden, in the ensuing summer, will take place on the following days, viz., May 28, June 18, and July 16. In addition to the regulations already announced, it has been resolved that the Judges be instructed, in making their awards, to take into consideration, whether the Plants to be judged have been exhibited previously during the season. Full information concerning these Exhibitions can be obtained upon application at 21, Regent-st.

The Gardeners' Chronicle.

SATURDAY, JANUARY 20, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Jan. 24.	Meteorological	.	8 P.M.
" "	Society of Arts	.	8 P.M.
Friday, Feb. 2	Botanical	.	8 P.M.

THE vegetable kingdom, as well as the animal kingdom, is subject to DISEASE. We need not here define very accurately what disease is. When it occurs in ourselves, we are quite aware that the functions of our frame are not carried on in the usual way. It is the same with plants. When any of the functions by which their structure and reproduction are maintained become deranged, disease is said to be present. Although the diseases of men and animals have been investigated with great care, and animal pathology and morbid anatomy have assumed an importance equal to animal physiology and anatomy, yet the same attention has not been given to the pathology of plants. This cannot arise from the want of facts to investigate, or the small importance of the subject, as every one with a garden is perfectly aware of the frequent occurrence of diseases amongst plants, and their destructive consequences. Of some of these diseases and their depredations we have many scattered notices; but, as yet, no work has appeared on the diseases of plants in the English language. This subject has not, however, been so much neglected on the Continent, especially in Germany, where Wiegmann, Bischoff, Meyen, and others, have produced treatises, more or less perfect, on the pathology of plants. We purpose from time to time to draw attention to this subject in the *Gardeners' Chronicle*, and shall endeavour to furnish our readers, in a form as systematic as we can adopt consistently with the most important facts that have been observed on the diseases of plants, and endeavour to lay down some principles for their cure and prevention. In this work, we hope not only to have the approbation, but the assistance of our readers. Just as in the study of medicine, every well-recorded case is of importance toward establishing the principles of human pathology, so every accurately-observed case of disease in plants will assist us in the work we have before us. As we proceed, we shall endeavour to point out the most important circumstances that should be attended to in the observation and relation of particular instances of disease. Wherever it is practicable, we should always prefer that all accounts of diseases of plants should be accompanied by specimens, which may be sent to our office, Charles-st., Covent Garden.

Before proceeding to any details on particular diseases of plants, we shall make a few remarks on their classification, causes, and treatment; and 1st, of their classification. We may arrange the diseases of plants in several groups, according to their situation and causes. When arranged according to their situation, those are called *general* which attack the whole plant, and those *local* which invade only a part. Such a division is, however, difficult in practice; as the same diseases may be either local or general. A better division of them is founded upon the apparent causes of disease. In this manner, we can divide them into four groups.—1st, Diseases arising from mechanical injuries; 2d, from the growth of parasitic plants; 3d, from a change in the external conditions of life; and 4th, from the influence of poisonous agents. To the first class belong all those diseases which arise from the accidental wounding of plants, the injuring of them by the various species of Mammalia, whether wild or domesticated, birds and reptiles, and the attacks of insects. To some of the diseases thus produced attention has lately been paid in Mr. Curtis's articles on Entomology. Wounds, however, frequently induce diseases, of which we shall have occasion to speak. To the second class belong the diseases produced both by flowering and cryptogamic plants. The former are not numerous, and of these the growth of the Dodder is probably most injurious in this country. The latter constitute a large group, and to them must be referred those destructive and frequently epidemic diseases known by the names of brand, smut, rust, &c. To the third class belong all those diseases which arise from the redundancy or deficiency of the various external agents necessary to the existence of plants, such as the [illegible] of [illegible], heat, air, moisture, &c. [illegible] a large number of diseases [illegible] and local, which generally consist in a deficient or excessive development of the functions of plants, or a change in their chemical character. It is to this class of diseases that we shall first more particularly devote our attention. To the last class belong all those diseases produced in plants by the action of injurious gases in the atmosphere, or of substances in the soil, which being taken up into the plant interfere with its healthy functions.

From the diseases of plants must be distinguished what are called monstrosities; the one may frequently run into the other, and it is not uncommon to find diseased plants exhibiting monstrous parts; but at the same time we do not intend to enter upon the subject of monstrous growths, which belong rather to physiological than to pathological Botany. In our next article we shall make some general remarks on the causes and on the treatment of the diseases of plants.

THE extraordinary mildness of the latter part of the past year has had the effect of throwing most collections of POLYANTHUSES into premature bloom; consequently, the Amateur will experience some disappointment, at the usual time of flowering, from his plants being weakened, unless he has taken the precaution to remove the trusses as they appeared.

Taking into consideration the quantity of seed sown in various parts of the country during the last 20 years, the number of fine varieties at all approaching the standard of perfect roundness, combined with perfect lacing and bright colours, are very few indeed. Still we trust that the impetus given to raising seedlings, from the best flowers only, will extend to "this," one of spring's gayest attendants.

We well recollect the time when Tantarara was most extensively cultivated; and though a coarse flower, it had properties which we should wish to see more strongly apparent in many varieties which have been originated since that period. It was a strong and luxuriant grower, though, from the unfrequency of its appearance, we should imagine it lost to most collections.

Alexander, which we understand was raised from seed by the late James Lee, of Lenton, near Nottingham, and the stock purchased by the late Jno. Pearson, of Chilwell, some 10 years ago, still retains its prominent position, and has taken during that time more first prizes than any other variety in cultivation. Its body-colour is intensely dark, combining with a beautiful lemon eye a corresponding margin of the same lively hue.

In our time we have seen thousands of seedlings bloom from this favourite sort, but none that have yet come under our observation have been so good as the parent, being generally coarse and undecided in character. Had they, however, been crossed with Buck's George the Fourth, we should probably have had a different result, for were we to select a variety to save seed from, the above flower would most certainly have the preference. It may be said the body-colour is of a coarse reddish-brown, and that at times the edge or lace is imperfect; still its habit is good, being a magnificent trusser, joined to one of the most perfect shapes we have; and did it possess the jetty body-colour of Alexander, with the correct lacing and brilliant yellow of Hufton's Lord Ranelift, it would most assuredly come nearly up to our ideas of a perfect flower.

Amongst the few seedlings which have come prominently into notice, and found their way to the south, during the last ten years, are those which have been raised by the late John Hufton, of Shipley, Derbyshire. Taking them altogether, they are certainly of a superior cast. His Lord Ranelift is one of the most robust habit, and increases prodigiously. Its trusses are large, but its flowers individually are below the medium size; still its ground or body-colour is extremely dark, contrasting beautifully with its bright centre and perfect lacing.

Earl Grey (*alias* Clegg's Lord John Russell) is also of the same paternity, and a great favourite. This flower is remarkably neat, and a good and decided variety. Its defect is a slight foxiness or indistinctness where the body-colour breaks off at the centre. That is, however, almost imperceptible, except to the critical gaze of the experienced florist. The lacing is distinct and regular, the flower above the middle size, a fine trusser, and very robust and luxuriant.

Squire Ray (Hufton's) is quite of first-rate character, joining to all the good qualities of the preceding varieties a beautiful trumpet eye, or tube, well filled with thrums; but perhaps the gem of the collection is Hufton's Lord Lincoln, which unfortunately, like too many other good things in the same way, is delicate in its habit. It is of beautiful and perfect shape, with its other properties finely developed. Much confusion has arisen in Derbyshire and the neighbouring districts from the circumstance of a spurious sort having been put into circulation by unprincipled parties. The true one, however, may be readily distinguished by the heart-leaves being invariably small, and at the same time having a darkish diseased appearance. As we intend to resume our observations on the Polyanthus very shortly, we shall close the present remarks by observing, that in the numerous catalogues of this flower which come under our notice, we miss several that some years ago gave us much pleasure in the collection of the late Mr. Thomas Hogg, of Paddington. If our memory does not fail us, they were Pearson's Wooden Walls, remarkable for its fine dark plum-coloured ground; Pearson's Harlequin, with a body-colour of shaded crimson, often coming; the Collier's Princess Royal, with six petals, Pearson's Commander-in-Chief, and Pearson's Competitor.

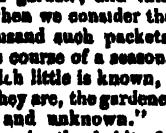
Should these varieties be lost, and we much fear it to be the case, as from inquiry we find that they are not now grown in the neighbourhood where they were raised, it will be much to be deplored, as they were all of fine habit and of good size, and were certainly decided acquisitions.—*W.*

To the honour of our country it may be said that all CHARITABLE INSTITUTIONS are sure of support if they deserve it, and it is no disgrace to British feeling if in some cases charity is misdirected. Such an army of Hospitals, Almshouses, Asylums, Schools, and Benevolent Societies as are maintained by private assistance in this kingdom is without a parallel elsewhere. We trust that every year their number will be augmented for as wealth increases, so, alas! does destitution; indeed, the one is, we fear, the inevitable result of the other.

If there is any one class of persons more peculiarly an object of compassion than another, it is surely that of aged Gardeners, whose lives have been spent in contributing to the gratification of the wealthy, while their wages have been far too small to enable them to make suitable provision for old age; for it is to be recollected that a gardener is not a mere machine, like some classes of servants, but a man, who, if he is to maintain his station in his profession, must of necessity incur expenses from which the menials of a household are exempt. He must have his books—he must buy the current knowledge of the day—he must visit his neighbours' gardens—he must spend his little earnings in fifty things of which the eye of the public knows nothing, but all which draw heavily upon his very scanty resources; so that when the hour of adversity arrives, as it may to any one, he can have no resource to fall back upon. We therefore conceive that the Gardeners' Benevolent Institution, of which a recent meeting a report is given in another column, most peculiarly claims the sympathy and support of the wealthy classes: we wish we could say that it had received it. Up to the present time, however, it has been mainly carried forward by Nurserymen, or by Gardeners themselves; for the contributions of other persons are too inconsiderable to deserve mention. Let us hope that those to whose comforts gardeners so largely minister, will now step forward and assist the funds as they already contribute to more fashionable charitable endowments. The little stock of about two thousand pounds, which a few poor persons have up to the present time amassed for the best of all purposes, the assistance of respectable old age, is less than is gathered at a single meeting of a fashionable hospital. The least possible move in favour of this charity among the wealthy would at once decuple its resources. Let us then entreat the great and wealthy not to wait to be canvassed, but at once to stretch forth their bountiful hands to the Gardeners' Benevolent Institution, of which none can be more deserving of substantial assistance. We shall be most happy to receive subscriptions and announce them in our columns.

While we say thus much for the English association for the relief of poor *and aged* gardeners, we must by no means omit to notice the existence of a similar institution in Ireland, which we are glad to find from a report before us is moving on satisfactorily, although very slowly. The committee of the Gardeners' and Stewards' Provident Society of Ireland state that it is in "a most prosperous state," and upon reference to the published accounts, it appears that the receipts for the year amount to the sum of *ninety pounds* for all Ireland. If this constitutes prosperity, let the rich Irish Landlords only consider how valuable to such an institution the smallest donation must be, and how easily they may win the gratitude of their fellow-creatures, at an expense, of the occurrence of which, even annually, they cannot by any possibility be conscious.

SEEDS OF GARDENING.—No. III.



(Continued from page 20.)

From oft-repeated examinations, I can assure you it is difficult to find [illegible] your purest seeds, and still more so to find parcels that are free of filth of every sort. And the more you examine your seeds, the more necessity you will see for picking them all clean, and administering them in such form as neither moth nor mouse can come at them.

But as these remarks will, perhaps, have little weight with an extensive class of your readers, I must reason a little closer, and try to bind it, if possible, to the services of Horticulture by threads drawn from other

…knowledge of art already familiar to the minds of all; but before any improvement is contemplated, let me state the matter as it stands now. The seed-grower harvests the crop, and frequently, for a very sorry remuneration, hands the seeds over to the wholesale seed-dealer, who again hands them to the retailer, and in the stores and granaries of these gentlemen seeds generally get on good. About Christmas or soon after, seeds come into the hands of the users; and now they are placed on shelf and in drawer, in canvas bags or in brown paper, in an atmosphere cold and damp, or dry and musty, just as the shed or garret may chance to be where they are stowed; and the seed-rooms of many of our boasted garden establishments are like the sheds, or more properly shellings, for the workmen and their tools, lamentably mean and ill-arranged as regards furnishing, ventilation, and dryness. I could scarcely find a room in any of them that I am acquainted with fit to keep a bag of seed in; for a seed cabin, or cabinet, should be dry without being hot, and ventilated without being open to wind and weather. This dryness and ventilation seems essential to the welfare of seeds to which the air has access, and cannot be overlooked with impunity in the keeping of loose seeds, of which the following are examples:—An ounce of Broccoli-seeds came to hand (not in a bag) in a square of brown paper, folded twice, turned up at the ends, and marked, in words more or less misspelt, with its quantity and name. This packet, with 11 others, had a brown-paper round them, and a string which turned the dozen out of the seed-shop very decently, but unfortunately only three or four out of the dozen had to be opened at one time, and of these only a small portion, say half, or perhaps only one-fourth, leaving the rest in confusion, unseemly driblets dragged from the jacket pocket of the sower, in untied, ill-folded papers, liable to be upset by the wind, or wetted by the rain, in a basket on the ground, in the open garden, and this confusion is wonderfully increased when we consider that not a dozen, but little short of a thousand such packets go through a gardener's hands in the course of a season, and of these many are novelties, of which little is known, and that little only by a few; yet here they are, the gardener and his novelties, "alike unknowing and unknown." The Horticultural Society has long been in the habit of sending a printed label with the name and properties of the articles pasted on the samples of seeds sent to the Fellows annually. I am glad of this, for it serves as a precursor to a more systematic arrangement; thus far and no farther have we progressed, December, 1843. Now let us proceed anew.

Every packet of seeds that comes into the gardener's hands should be in tin boxes, each box having on the lid the name and date of the sowing of the seeds, and likewise a number or mark of reference to the name of the grower of the seeds; or, which is better still, a seal securing the safety of the package, stamped with a representation of the plant whose seeds are inclosed, and the initials or name of the grower or vendor who guarantees their quality. Such precautions would enable honest men to trace good things to their source, and bad ones to their author, and act upon the hints so gained in buying seeds for the future, and I can see no reason why seed-growers should send out seeds so slovenly to the world as to be liable to mixing and injuries of all kinds, whilst such as Curtis and Harvey send out gunpowder—of less value than garden-seeds—in close tin-cases, well wrapped in paper, and beautifully labelled with letter-press and picture, setting forth the manufacturers' address and specifying the uses and degree of fineness of the inclosed grain. Some foreign growers send Stock-seeds to this country in sealed red leather pouches, so you will perceive that I am only wishing to perfect a system already begun. Supposing, then, the lid of the tin box containing seeds to stand thus—

and the number 2213, to signify in the vendor's book the name of the person that saved the seeds, or else to have his seal; in which latter case his seeds would be encased before he sold them, and sealed to prevent imposture. But this is not all; for around the tin box there must be another label with the names, botanical and popular, of the article inclosed, with its character and uses according to the best practice; this would convey the information home to the user, and as the seed-grower is never loth to tell the seed buyer the good qualities of the plants of which he has the seeds, there can be no difficulty in coming at the kind of information I speak of; and when once written, it can be printed for the veriest trifle now-a-days, and the cost and labour, with tin boxes and printed labels, will not be one whit more than under the present system of packages in canvas and paper for the following reasons.—The boxes in which Walker sends out 500 of his percussion caps came first to my hands as a handy sample-box. I weighed two ounces of Yellow Mustard, and found this small box (which I inclose) to hold it [illegible] the key to our tinman and brazier, Mr. Mellow of Uttoxeter, and he said he could supply such at less than 1d. each. These boxes, therefore, may safely be taken as large enough for single ounces of ordinary seeds. The next tin box that came to my hands was one of Hill and Co.'s Presburgh wine-biscuit-boxes. I found it to contain nearly half-a-pock of Yellow Mustard, and the value of this box is 4d. Here, then, is a quart of seed-containers for 1d., four quarts for 4d. Mr. Hill has, moreover, set forth some useful hints on his biscuit-labels. His says if the [illegible] are kept dry and in their packages, they will retain their delicate uniformity during a long voyage; nor will the change of climate deteriorate them." Mark this; his bread is not mouldy for a year or two, because he packs it properly. Our barks and seeds, if similarly treated, might fare the same.—*A. Forsyth, Albion Towers.*

THE ROSE-GARDEN.—No. I.

The best work on the cultivation of the Tree-Rose with which we are acquainted is one published in the year 1830, with the following title

"PRACTICAL INSTRUCTIONS
FOR
THE FORMATION AND CULTURE
OF THE
TREE-ROSE,"
BY INOCULATION AND GRAFT UPON THE WILD BRIAR
Illustrated by Twenty four Woodcuts

"Parva leves capiunt animos"

Notwithstanding its value, this work is scarcely known. Here and there an amateur possesses it, and appreciates its excellence, but by the majority of people it was never heard of. We have now the satisfaction to announce that the copyright has been purchased for the use of this Paper, in which the whole Volume will appear in the course of the year, in a series of weekly articles, with numerous corrections and alterations by the talented Author *A. H. B.*

"*Preface.*—When a traveller gives an account of the country he has been wandering over, he frequently delays writing his description until he has been somewhat accustomed to the place, its manners, customs, and inhabitants; and thus, instead of mentioning what struck him at first sight, and is, in reality, the most amusing and instructive, he publishes his work as a hard outline, deficient in those light shades and fine touches, without which his picture is unequal and incomplete.

"Thus it is with writers upon experimental subjects. They frequently suppose that a certain quantity of technical knowledge is previously in possession of the reader, and omitting some necessary part of their descriptions upon this assumption, the theory to the reader is incomplete, and baffles his endeavours to act upon it.

"With a desire to avoid these errors, the memorandums in the following pages have been noted down from time to time, they are the result of an examination of all the works upon the subject accessible to the Author, during a practice which commenced in perfect ignorance, and ended by almost certain success.

"The great inducement to collect together the following remarks arose from the observation of the frequent failure of common Gardeners, who usually act from practice alone, and therefore do not always vary their operations as often as the changeableness of the year and the nature of the place in reality require.

"A fact aptly illustrated by a failure in eleven cases out of twelve in the first experiment on this subject witnessed by the Author, though the operator was called an experienced hand.

"Be it observed, that while the Author acknowledges himself indebted for much matter, and almost entirely for arrangement, to works published upon the subject, especially to a small pamphlet lately published in France, yet it is upon his own practice and observations that he depends for his assertions, and from his own failures (partial or entire) that he endeavours to point out the deficiencies likely to prevent success, and the means and observations requisite to improve upon it.

"Amongst the amusements of the most refined and elegant minds, those which have some reference to the productions of Nature are perhaps the more satisfactory, both in practice and result.

"Ornamental scenery, the culture of exotics, the laying out of pleasure grounds, &c., are matters which involve a considerable expense, both in commencement and continuance, though perhaps only indulged in to a small extent, but the *gradual* [illegible] improvement of a place, by adding to the number of ornamental shrubs, filling up vacancies, &c., is an amusement, indulged at a less expense, requiring only occasional assistance, a little method, and a few implements for the purpose of propagating the species desired, many of which will bear to be transplanted repeatedly, and, costing little at first, are fit subjects of practical amusement to those who like to have such matters under their own especial eye, and are interested in them in proportion as they themselves can appreciate and attend to them.

"*Introduction.*—Amongst the ornamental shrubs in cultivation, the Rose has long been the favourite, from its shape, permanence, the variety of its species, and the brilliancy of its colour; one thing, however, remained desirable, viz., that the unsightliness, as it were, of the plant should be corrected by its springing like most other ornamental shrubs (which are not feathered to the base) from a single stem. As well as that its height should place it above the other shrubs which (particularly evergreens) would otherwise hide, choke up, and injure the plant.

"The mode adopted to gain this point, which has also added to the beauty and regularity of the plant, as well as to the profusion of its flowers, (though it is said to have injured its durability,) will be treated upon in the following remarks, together with the means of preserving the health and improving the appearance of the tree.

"There appear to be but three reasons for entering into competition with mechanics in any branch of their work: the first, to effect our own purpose, with our own hands, and thus furnish ourselves with occupation and amusement; the second, to avoid the expense attending the labour of others; and the third, and more difficult, to improve upon the manufacture, by dexterity of operation, care in completion, and choice of material.

"I shall endeavour to show that these points may be perfectly obtained: the first, by the insurance of success to the operator from a clear and comprehensive view of the subject; the second, by a diminution of expense; and the third, by an evasion of those deficiencies which are the result of scanty labour and general inattention.

"The usual price of a tree Rose is from 5*s.* to 10*s.* 6*d.*, the materials required to make any quantity are few, of little or no value, and the Stocks* themselves are procurable in any number, at any price, in the country.

"Rose trees, properly treated, rarely perish in a good soil, and when they do, it is in general during the first season, and before any trouble has been bestowed upon the Stocks. As the Stocks will be picked, they will more than equal those in common use, and being subsequently budded upon, according to their size, health, and fitness for the species they are intended to carry, the success will be more complete than when no selection is made in the material, and the cultivation is confined to a demand for particular species, and the labour and time bestowed upon them, limited by a due regard to the per centage they are intended to return.

"The injury from wounds, also, being commensurate with the first planting the Stock in the salesman's nursery, the damage done to it by the time it has become ornamental is frequently irretrievable, and the tree vegetates weakly for a season or two, (especially if small,) and then dies, or is broken off by the wind. This, a careful attention to the following rules will effectually obviate."

(To be continued.)

LISIANTHUS RUSSELLIANUS.

This fine annual, introduced from Texas in 1835, is still uncultivable in the hands of many good gardeners; yet we occasionally see noble specimens on the exhibition tables near London, a sufficient proof that the plant may be grown well under proper management. Among the most successful cultivators of it is Mr. James Cuthill, florist, Camberwell, who has put into our hands the following account of his mode of treatment.—The best time to sow the seed is in March, and as the seed is extremely small it requires particular care. If deposited in the usual way, upon loose soil, the first watering carries the seed along with it, and hence the failure. Prepare the following compost—half loam, the other half leaf, peat, or bog mould, with a little sand, place plenty of drainings in the bottom of a 48 or 32 pot, fill it with the compost very tight, and on the top place half an inch of sand; damp the sand with water to harden the surface, sow the seed, and sprinkle a very little dry sand on the top. Place a propagating-glass over the pot, or a piece of glass will do, place the pot in a heat of 70° or 80° with a pan under it for future watering, at no time water on the top, the pan ought never to be allowed to get dry. The seedlings will appear in three weeks or more; when about three weeks up, plant them singly in a 60 pot in the above compost, with plenty of drainings in the bottom. Place them again in the back of your Cucumber pit or frame, after this you cannot give them too much water over head and in the pans, and by the autumn, if they have been kept in a good growing heat, they will be fine little bushy plants. Top them at every joint; in September shift them into large sixties, merely to keep their roots in a more intermediate state for the winter; after this all top watering must cease, and a pan must be placed under each pot to receive the watering. As the winter approaches not a drop of water must be allowed to fall on the plant. The drier the top mould, and the leaves and stem, the more certain of preserving the plant. The best place I have found is a one-light pit, heated with a lining of dung from 50° to 60°; air given front and back, so that no damp can fix on the bars and drop on the plants. The second best place is the coldest part of the stove, very near the glass. I have also kept them well in the warmest part of the greenhouse. In all cases water just sufficient to keep the plants from flagging in the winter is dry, once a fortnight; if damp, quite enough

ed in. Towards the end of February place them in a Cucumber pit or frame, in a heat of from 70° to 75°, and when they begin a fresh growth shift them into as large pots as convenient, remembering the larger the pot, the finer the specimen; my largest plant had 600 blossoms on it, and was grown in a No. 8 pot. As the spring advances it is almost impossible to give too much heat and moisture. They are very fond of liquid manure. It is useless to grow a fine plant in any place approaching to dry heat, nor in less than 70° to 80°. I have grown them 6 inches in 7 days. In removing out of the pits, great care must be taken not to allow the sun to shine on them for some days, as the change from a damp close heat to a dry house will be too much for them. By the above treatment they will come into flower about the middle of July, and keep blooming from two to three months.

ENTOMOLOGY.—No. LIII

THE ELM GALL APHIS.—The Plant lice are so familiar to the gardener, that to enlarge upon the mischief occasioned by them is quite unnecessary here He will, however, find in a recent Memoir laid before the Royal Agricultural Society, the serious effects produced by some of the species upon the Turnip and Cabbage crops * The Aphis before us is not one of those which blight the fair prospects of the cultivator, it merely disfigures the trees, and it is doubtful whether it be an inhabitant of this country, as however it affects an English tree, it may have escaped observation, and as the gall or nest is very remarkable, and has never been noticed in any British work, it will prove an interesting addition to our knowledge of this family of insects.

In my rambles about Rome I first observed these excrescences (fig 1), and afterwards in the neighbourhood of Tivoli, I saw them abundant in hedges leading to Adrian's Villa, this was about the middle of June, and they were attached to the long young shoots of the Elms They varied from the size of a Walnut to that of a large Apple, and were produced at the apex of the short lateral twigs, whose growth was thereby checked, the gall being formed at the expense of the leaves. These excrescences are very light, the external surface is exceedingly uneven, leathery, greenish, and not thick; being hollow, with a considerable quantity of fluid inside, and containing at that season multitudes of the Aphides. The fluid, which was perfectly limpid, flowed in great quantities from the galls of the specimens attached to the branches which I cut off, and when the liquid dried it became gummy

The only gall which had previously come under my notice bearing any resemblance to this in its formation, was that of the Aphis Bursaria of Linnæus, which I shall describe and figure in a future Number, but the Cabbage leaves become distorted and crumpled in a similar way by the operations of the Aphis Brassicæ Linn † There seems to be three species of Aphides which affect the Elm trees —one induces the leaves to roll up, another forms a stalked gall beneath the leaf; and a third causes large excrescences to be developed upon the buds. All these have been confounded by Linnæus and Fabricius under the Aphis Ulmi, but it may be fairly presumed that these galls and distortions, varying so greatly from one another, are the productions of as many varieties of the Aphides.

We will now describe the Elm-tree gall Aphis, which has been named by De Geer "Aphis Gallarum Ulmi." The rostrum is scarcely so long as in the genus Cinara; but it appears to be stouter at the base; the winged females are deep black, powdered with white (fig. 2), the antennæ are filiform and short, composed of several joints, elongated at the base, and decreasing in length to the apex; wings four, superior, very large, transparent, with a blackish oval stigma; nervures pallish, forming an ovate marginal cell; the second furcata at the posterior margin, and not resembling the subcostal nervure, the other two oblique; inferior wings much smaller, with a subcostal and two oblique nervures; legs six, not very long but slender; tarsi short, biarticulated, terminated by two minute claws. The apterous females are brownish, the apex of the abdomen a little woolly; the ducts very small, forming tubercles only; legs and antennæ short; some of the adult ones are broad behind, and powdered all over. The pupæ are more elongated, with the rudimentary wings already applied to the base of the abdomen. To complete the metamorphoses there is added the eighth figure, which is one side of the insect is represented in the out; [illegible] four wings and six legs; the thorax has [illegible]

* Vol. iii. p. 49. † Ib., 51.

exhibit the natural size when the wings of the female are expanded, and it is presumed that the males are similar, but I have not met with that sex.

This species is allied to Eriosoma, from which it is readily distinguished by the forked nervure in the superior wings, and forms the transition to the genus Cinara,‡ but the oval stigma is a character not to be found in that group or amongst the Aphides § From its economy I expected to find it closely allied to E Bursaria; but it does not belong to the same group, and it makes the nearest approach to a species with a black stigma, which I find flying about Fir-trees in great abundance, and this may prove to be the A Pini of Fabricius, but as I am unable to determine this from his vague description and confused synonyms, I have called it C stigma Until the Aphides have been more completely investigated by scientific men, we must refer the 'Elm tree gall Aphis" to the genus Cinara, in which, with the C stigma, it will form a section, having a thickened oval costal spot, from its structure we may also learn that this group ought naturally to follow the Eriosomata of Leach, and that the true Aphides should not intervene, as they do in "Curtis's Guide" || The typical Eriosomata were thus characterised by the late Dr. Leach —"Abdomen without tubercles or horns, antennæ short and filiform; body tomentose" He adds—'The Eriosomata form what are called improperly galls on the stalks of trees near their joints, and knobs, which are in fact excrescences caused by the efforts of nature to repair the damage done to the old trees by the perforation of those insects whose bodies are covered with down" As an example of this genus he gives the E Mali, which is the Aphis lanigera of authors, and the American blight of gardeners —*Ruricola*

BEES.—No III.

(*Continued from page 21*)

Though Bees can be easily prevented from swarming, yet it is not profitable to do so indeed all systems that prevent swarming are bad and uneconomical The systems of Dr Bevan and Mr Nutt ought to be eschewed by all means Generally speaking, two swarms ought to be taken from almost every stock hive every year In an extraordinarily rainy year it may be injudicious to take a swarm at all, particularly from those that were very weak in the spring months. The period of the year at which swarming should be prevented will vary according to the season and locality In Middlesex, for instance, hives cease to increase in weight about the beginning of September. Where this is the case no first swarms (whether virgin or not) should be taken later than the middle of July

Swarming is prevented by augmenting the hives, and the most profitable modes of doing it shall be noticed by and by. At present I would chiefly direct attention to the artificial system of swarming, which supersedes the natural system It is thus accomplished —Blow a little smoke from a bit of fustian or corduroy rolled up in the form of a candle (which ought to be used in handling hives) into the hive, place it on the ground inverted, a few yards from the stool—put an empty hive on it, and fasten a cloth round about the hives to keep in the Bees: the hive prepared to receive the swarm must now be placed on the board whence the stock was taken then drum or rap with open hands on the bottom hive for the space of 8 or 10 minutes—untie the cloth, take off the upper hive, and put its crown on the ground Spread the cloth over the combs of the old hive, and now look amongst the Bees which are thus drummed up for the queen As soon as you see her, give the hive a violent shake and tumble the swarm into the struck hive, in the same way in which you would put Peas out of one basket into another. If too many Bees are drummed up put the queen into the struck hive with a spoon, or your hand, in order that she may not be amongst those that are returned to the stock-hives So many Bees as will barely cover the combs ought to be left Place the colony a yard to the right—the stock a yard to the left of the old stool You need not be afraid that the Bees will not hatch queens, and that it requires a greater degree of practical adroitness to accomplish this than you possess All that is necessary is a willing mind. This system has, for more than 30 years, been adopted in one of the largest and most profitably managed Apiaries in the British Empire It is impossible to form an adequate conception of the advantage of the artificial over the natural system. When the artificial system is adopted, no swarms are lost; Bees are prevented from clustering and mispending their time outside, attendance is rendered unnecessary, more second swarms are obtained, and the honey may be taken from the stock on the 21st day from the time the first swarm was taken off, without either Bees or brood being destroyed.

"While I would recommend this system of artificial swarming, I would condemn that system which Dr Bevan has recommended at p. 157 of "The Honey Bee" His system is the following —"Towards noon of a fine day, or almost at any time, if the Bees cluster out much, let a stock-hive be removed to a distance, and a spare hive or box be put in its place, to one box of which is attached a comb containing workers' eggs, or very young larvæ of the same sex, the outhers, or the Bees that are abroad, or both, as the case may be, will then enter the new habitation, cluster round the brood, construct one or more royal cells, inclose one or more eggs, and raise a young sovereign; and thus, if the season be favourable, form a flourishing stock." I doubt very much whether this can be accomplished; for the Bees, if thus dealt with, would raise two or more sovereigns or princesses, and with one thereof send off a colony on the 13th day after the eggs were put—that is, on the 6th day after the princesses are matured. In some cases a swarm may not issue, but even then it would not "form a flourishing stock," for the combs constructed under these circumstances would consist chiefly of drone-cells, the Bees being apt to construct this sort when they have one or more queens in embryo. In taking off second swarms a little caution is necessary, for if the queens should be matured they will burst out of their cells as soon as you begin to rap, and it may happen that all of them go with the swarm; but by taking a swarm off as soon as one queen only is matured, attendance becomes unnecessary, and the queens take the drone, and consequently commence to lay two days sooner.

Some Apiarians think that it is not profitable to take second swarms, but all who keep their Bees in large hives think differently. When you come to know that, if Bees are kept in large hives, every family, in fair weather, before the first swarm is taken off, gathers from two to five pounds of honey every day, you will say with me that artificial swarming is, in a pecuniary point of view, the greatest invention that can be found in the annals of Bee-history; and that it is extreme folly to allow Bees to cluster and squander their time about the door of the hive Lady Apiarians who are unable to take off swarms would do well to employ some person who is able to do so for them, though he charged half-a-crown for the taking off of every first swarm

Second swarms do not leave the hive from want of room; and for this reason, augmenting the hives will not prevent their coming off Cutting out all the princesses but one (when they are in their cells) will prevent a second or third swarm from being thrown, but this cannot be accomplished in every hive To be sure, throwing a swarm of this sort back will cause it not to issue again, at least in 99 cases out of 100 But about the second or third week of July, which is the time to prevent swarming, there are plenty of queens ready, or nearly ready, to burst out of their cells, either in your own or your neighbour's hives. Well, then, whenever you take off a first swarm, about the middle of July or earlier, if you do not want a second swarm, cut out of another hive a cell that contains a queen, and put it in the hive whence the swarm was taken If the queen be matured, take off the lid of the cell and let her run into the hive, but if she is not fully ripe turn up the hive and fix the cell between two combs This is an item in Bee management of first-rate importance, for the queen, thus introduced, will soon begin to lay, whereas, if the Bees had been allowed to rear a queen, there could not have been any eggs laid sooner than the 24th day from the time the swarm was taken off If stock-hives are about 40lbs. weight when the first swarms are taken off, it is advisable to let the Bees rear queens, in order to obtain the honey before the young queens commence to lay The Bees of stocks are put into second swarm size hives, and are termed "turn outs" Sometimes the stocks are kept in a garret, or in some out-of-the-way place without Bees [illegible] September, when they are brought to the Apiary and furnished with Bees —*A. Pettigrew, Wrotham Park, Middlesex.*

Home Correspondence.

Pseud-Acacia.—I saw in the *Chronicle*, lately, a communication from Mr P. J. Selby, respecting the Pseud-Acacia, and as I was some years ago interested in shipping I paid much attention to the qualities of the timber of which vessels were constructed; it was at that time the highest recommendation of an American vessel to be built of "live Oak, Locust, and Cedar" The late Mr. Cobbett, who was so energetic in his recommendation of the culture of the above tree, was perhaps not aware of a fact well known to many of the ship builders of New York, viz, that the durable properties of the timber depend very much on the soil and situation where it is grown, and his experience of it was probably derived from his residence on Long Island, a great part of which is well adapted to produce the qualifications which he attributes to it. The situation best calculated to give to this timber the property of durability is the vicinity of the sea, and I believe that Locust timber, grown out of the range of the immediate influence of the sea breezes, will not have the property of durability in the perfection described by Mr. Cobbett. The size to which it attains, and the rapidity of its growth under favourable circumstances, (probably of a rich alluvial soil), I do not think was more exaggerated than was usual in the writings of the above author, who was noted for taking a sanguine view of every subject and for writing in a strong nervous style and to its durability I can bear testimony, from experience of the state of treenails (wooden bolts) which had been upwards of 30 years in a vessel, and which were so sound as to admit of being backed out by means of an iron drift bolt when the vessel was brought under repair From the straightness of its growth in the lengths (15 inches to 3 feet) generally used for treenails, and from its property of splitting truer to a size than most other woods, coupled with its durability, it is a favourite fastening for vessels. The Acacia or the Locust is not singular in its fondness for the neighbourhood of the sea The Live Oak, it is well known, flourishes best—nay, it is seldom seen of any size elsewhere—on the coast of South Carolina and Georgia, and more especially on the small islands which are so numerous along the coast between certain latitudes; in fact, wherever the "Sea Island Cotton" flourishes, the Live Oak is in the greatest perfection.—*Acacia.*

Orchidaceous Plants.—At p. 7 of the *Gardeners' Chronicle* "D. B." states in the Calendar of Operations, that Orchidaceous plants "need not be watered or entoned to grow for a long time." I should like to know how long he means. It is not only a duty incumbent on every gardener to study, as it were, the nature of his plants, but also to become acquainted with the changes of

the seasons to which they are subjected in their native countries, and it is a matter of great importance to know the length of the different seasons suitable for the Orchideæ generally cultivated in our stoves. In Brazil, Mexico, the East Indies, &c. where many of them are found, their season of rest is rarely more than six weeks, when they begin to put forth young shoots; and this, according to the laws of nature, shows that they require what is an early season of growth, in order to have light and heat to mature their pseudo-bulbs after they are of proper size. Therefore, owing to the shortness of our summers, Orchideæ ought to be encouraged to grow early in spring, and receive their season of drought as early in autumn as possible. This I find to be much more advantageous than if they were in a growing state in the month of November, when water must be withheld, to keep the unripened bulbs from damping off. Were I to act according to "D. B.'s" directions, and begin to entice my Orchideæ to grow in the month of May, which I consider to be "a long time," next year I should have young shoots damping off, pseudo-bulbs shrivelling, and the plants one-third less than what they were last year.—*Basilicus Fibræ.*

Destruction of Snails by common Salt.—Having strewed some common salt upon the ground, I placed a number of snails amongst it; all those that came out of their shells and touched the salt, immediately threw out a green-ish globular froth, and in a few minutes were dead. I think this fact may be turned to some account amongst farmers and gardeners.—*J. M. T., Hillsborough.*

Twine for fastening Wall Trees.—In training plants and fruit-trees to the wall I have for some time used twine dipped in linseed oil, and dried, instead of bits of cloth; it is neater, more convenient, and affords no harbour for insects. Drive the nail into the required place, slip a tie with the twine over the head, bring the branch down and secure it with a knot. A tree secured in this manner is capable of being better trained, the branches better secured, and the whole appearance more workmanlike.—*J. C. B., Exon.* [We perfectly agree that twine used for that purpose would have a neat appearance and offer no harbour for insects, but it is objectionable because it is apt to cut the branch, and is on that account very productive of canker; it would also occupy much more time to fasten a tree to a wall with twine than by the common mode of using bits of cloth.]

Paint for Old Walls, &c.—The walls here are very old, and having had trees nailed against them for probably more than a century, they were covered with multitudes of nail-holes, and in those holes, no doubt, were numbers of insects ready to emerge and infest the trees. In spring it occurred to me that a wash for the wall would be of greater service than one for the trees; I therefore prepared a mixture of lime and Roman Cement, in equal quantities, in a fresh state, adding sufficient water to make it of such a consistency that it might be applied with a brush. This paint was put on in a fine day after the trees were pruned, and before they were nailed; this is the time I find most convenient for applying it. A great advantage in using this composition is, that it does no injury to the trees themselves. In order to ascertain this, I selected two young Peach-trees that had been the previous year severely attacked by green-fly, so much so that the trees were nearly dead; these I covered with a thick coating of the mixture, and in the following spring they burst through the paint with more than ordinary vigour. They are now as healthy trees as could be desired. If the walls are very bad, two coats of the mixture would be better than one; and if it is desirable to make it a little darker or lighter, the use of a larger proportion of lime or cement will effect the object. The inventor of the "Metallic Anti-corrosion Black Paint" strongly recommended to me that material for the purpose of painting the walls, adding that the fruit ripened a fortnight earlier on walls so painted. I was much afraid that by exciting the blossoms too early they would be more susceptible of injury by frost; but I have no experience in the matter, and should feel obliged for information respecting its application to walls.—*E. H. Kemp, South Lambeth.* [It does not answer to excite wall-trees unless some efficient protection is at the same time provided. But we doubt the fact of any kind of coloured paint advancing the maturity of fruit a fortnight. The experiment was fairly tried some years ago, and no advantage was discoverable.]

Lonicera Marryatta.—This is one of the best conservatory climbers, it is always graceful, and I never saw an insect infest it. It cares not for shade or sun; at the present time I have one covered with scarlet Pea-flowers, many of which have been expanded for three weeks, and many more buds have yet to open. Tropæolum pentaphyllum is also an excellent plant for the conservatory. Allow me to confirm what Mr. Beaton said about not opening the upper lights of a conservatory. If they are kept close tender climbers will bloom in perfection therein; last year I had Mandevilla suaveolens, Ipomœa Learii, Passiflora alata, in fine blossom during summer and autumn in a close house.—*Flora.*

Rhizomorphus.—The fructose root is found by labourers, trenching ground to a considerable depth; it is frequently encountered with any vegetable growing on the surface. It is not found in any particular soil, nor in the immediate neighbourhood of trees. One of the labourers says he has found it in light sandy soils, but the last root that was dug up in rich loam. The fructose root is not so tough as some that are found, but it always has a dead appearance. Could you kindly afford any information respecting it?—*Rusticus.* [This plant is undoubtedly much more common than Botanists suppose, for close research has produced many specimens which have been under our observation. It is a fungus, called Rhizomorphus medullaris, consisting of a white fibrils very little is known to Botanists.]

Hammond's Cape Broccoli.—A correspondent, "W. N." informs us that, seeing this Broccoli advertised in the *Chronicle* last spring, he purchased two packets of it, and sowed it at three different times; the plants all proved to be tender, although they were stated in the advertisement to be hardy enough to stand the winter. "W. N." imagines that he has not got the right kind. Will some of our readers say whether it stands the winter with them?

Cause of Mildew.—Having seen at p. 823 of the *Chronicle*, remarks by Mr. Wighton on the cause of mildew, I am induced to offer my opinion on the subject. Mr. W. observes,—"Supposing six practical gardeners were asked the reason why their Peach-trees were mildewed, they would most probably all assign it to different causes." He then states the supposed causes, viz.:—"Dry or damp situations, strong or light soils, or a Fungus either on the roots or on the branches." It is true that there is, perhaps, no subject connected with gardening on which the opinions of gardeners are more at variance than that of the cause of mildew. I do not, however, attribute it to any of the above causes. I believe that the Fungus which we call mildew on trees is not the cause but the effect of the disease, and that the disease is occasioned by a sudden transition of temperature. In my practice in Peach-forcing I have had no cause to complain of mildew, when the night temperature was kept in due connection with that of the day; but even under glass, without the application of artificial heat, I have had Peach-trees as much injured by mildew as any that I have ever seen upon the open walls. It must have been observed by every gardener, that the disease is most prevalent in spring and early in summer. At that season it is not uncommon here to have our temperature varying from 30° to 70° in one day. From the effects of low temperature the sap of the tender shoots becomes congealed, and when it becomes suddenly warmer this congelation is too quickly liquefied, and in place of circulating through its regular channels, it bursts forth through the pores of the young shoots and leaves, and the Fungus-like substance immediately follows. If the disease was occasioned by anything but variation of temperature, the result would be the same every year; but this is not the case, for we find trees and other permanent plants, the one year totally escaping the disease and the next almost destroyed by it. This goes far to prove that variation of temperature is the sole cause of the disease. Consequently there can be no preventing it, where there is no control over the temperature. Sulphur is sometimes applied as a remedy, and it kills the Fungus; but this, as above stated, is only the effects of the disease. Some imagine having destroyed this, and soon after perceiving their trees beginning to grow again, that they have effected a cure; whereas, in reality, this new growth is entirely the result of a more genial temperature.—*J. Gavin, Donibristle Park, Fifeshire.*

Societies.

HORTICULTURAL SOCIETY.

Jan. 16.—R. W. Barchard, Esq., in the chair. J. Stewart, Esq., M.P., was elected a fellow of the society. From Mr. W. P. Ayres, gardener to J. Cook, Esq., were two remarkably fine specimens of Epacris nivalis and impressa. Both plants were about 6 feet high and 3 feet in diameter, and were uniformly covered with blossoms. Mr. Ayres states that the treatment which they received during the past season differed much from what is usually considered proper for this tribe of plants. Instead of being grown in an airy greenhouse, they were subjected to a close moist heat of from 60° to 90°, with no more air than was necessary to keep the heat from exceeding what is above stated. After sunset, especially on dewy evenings, air was freely admitted; but the plants were syringed, and the house was closed before the sun came upon it the following morning. The rate of growth was said to be so rapid that to keep the plants from flagging they had to be shaded during bright sun-light. Many who saw them during summer said that they would not set any flower-buds; but the result proves that a fine show of flowers is not incompatible with luxuriant growth, provided the precaution is taken to get the young wood properly matured before winter: a Knightian Medal was awarded for them. Mr. J. Robertson, gardener to Mrs. Lawrence, sent an exceedingly fine specimen of Epidendrum nutans, about 7 feet high and 3 in diameter, bearing nine main-shoots covered with greenish blossoms; this is an old plant, and well known, but it is very rarely seen in such perfection as in the present instance, and is an evidence of what good cultivation and management can effect. There was also from the same collection a pretty plant of the showy Lælia anceps, having long slender flower-stems, on the points of which were situated its bright lilac and purple blossoms; likewise a plant of the scarce Cypripedium barbatum, and one of C. venustum, along with well-grown plants of Phalæ Tankervillia and P. Intermedius. Mr. Robertson also exhibited a pretty plant of Lælia autumnalis, and a well-grown specimen of Centradenia rosea; the latter, from Sierra Leone, is a plant of easy cultivation, and is exceedingly beautiful when covered with brilliant rose-coloured star-like flowers. It has likewise the good property of being a free bloomer. Plants of Batemannia Colleyi, Aspasia epidendroides, and Zygopetalum crinitum from the same collection, were also sent for exhibition; a Knightian Medal was awarded for the three first plants. Mr. E. Plant, gardener to J. H. Schröder, Esq., sent a fine specimen of Coryanthes maculata, having a pendant scape of about one foot and a half long, at the end of which were three fully expanded large, yellow-coloured blooms, beautifully spotted with purple. From Mr. S. Read, gardener to T. J. Lester, Esq., was an exceedingly well-grown specimen of Clerodendron splendens, having fine fragrant scarlet blossoms; this is one of our prettiest winter stove plants, and under good management it is an abundant bloomer; a Banksian Medal was awarded for it. Messrs. Veitch and Son, of Exeter, sent a small plant of a Gaultheria, named ferruginea, having considerable resemblance to G. Shallon; it was imported by Mr. Veitch from the Organ Mountains, through Mr. W. Jobb; the plant exhibited had been standing in a mild pit, and Mr. Veitch states that he has one planted out in the open border, and considers it sufficiently hardy to stand our climate. Mr. R. Ayres, gardener to E. L. Stephens, Esq., of Roehampton Grove, exhibited three sorts of Cucumbers, one of them the "White Spine" was a good fruit considering the season of the year; a certificate was awarded for them. From Mr. Beck of Isleworth, were good specimens of Ashmead's Kernel Apple; this is a very valuable hardy variety; it is much in the way of a Nonpareil, and from its being a great bearer, as well as on account of its general excellence, it is worthy of a place in every cottage-garden. Mr. Buck, of Blackheath-gardens, sent three sorts of seedling Pears, numbered 2, 15, and 18. From G. Crawshay, Esq., of Colney Hatch, were specimens of Black Hamburgh Grapes that were cut on the 15th of January; they were good bunches, with well-swelled berries; and although they had been grown in a Vinery without the aid of fire-heat, they were perfectly ripe and well-flavoured; he also exhibited a bunch of the same sort that was cut on the 4th of December last, and had kept in good condition hung up in a room; the berries were not at all shrivelled nor the stalks decayed. Mr. Crawshay grows his Grapes, as before stated, in a Vinery where no fire-heat is employed, except in very dull damp weather; small fires are occasionally lighted, not to increase the temperature, but merely to dry up the damp; the Vines are allowed to have great ventilation, and from this circumstance the Grapes are well ripened, which is the great secret of their keeping; a certificate was awarded for those cut on the 15th January. J. Moorman, Esq., of Portland Place, Clapham-road, sent a collection of Pears, among which were specimens of Napoleon and Passe Colmar in good condition: a certificate was awarded for them. From the Garden of the Society were flowers of Chimonanthus fragrans and grandiflorus, with a collection of Apples, consisting of Court Penda Plat, Reinette du Canada, Cockle Pippin, Pomme Royale, Boston Russet, and Golden Harvey; the latter is one of the best sorts in cultivation, in richness and delicacy of flavour it is even superior to the Golden Pippin; it is also remarkable for being an excellent Cider Apple. The tree is perfectly hardy; it is a good bearer and worthy of a place in every garden. From the same collection were likewise sent the following Pears, viz.: Easter Beurré and Beurré Rance, the latter were from standards; this Pear, although not so large, is found to be much better flavoured when grown in this way than when trained on a wall, unless a south aspect can be afforded for it. There were also specimens of Winter Crassane, an excellent variety raised by the late Mr. Knight; it not only resembles a Crassane in appearance, but also in flavour. It is a most abundant bearer, and so perfectly hardy that it does not at all require the help of a wall to bring it to perfection.

LINNEAN SOCIETY.

Jan. 16.—Edward Forster, Esq., in the chair. Dr. Thomas Harrison, Dr. Wm. Francis, Dr. Hamilton, Dr. Clement, and John Camplin, Esq., were elected Fellows. A specimen of the flying fish was presented by Mr. Green. Joseph Janson, Esq., presented specimens of the Sphæria Robertsii and of the fruit of Cheirostemon platanoides. An extract of a letter to Dr. Bostock from his son was read, giving a detailed account of a flight of locusts which he had witnessed in India, between Cawnpoor and Agra. The number of locusts was so great that the air became quite darkened. They appeared to be moving at about the rate of four miles an hour, and although the travelling party were moving in an opposite direction they were between two and three hours in passing through them. Professor Edward Forbes read a paper on the Echinidæ of the Ægean sea, of which he had found 12 species when accompanying Captain Graves in H.M.'s ship Beacon. The most remarkable of these were a new Amphidetus, allied to the A. cordatus, and the Echinus monilis, identical with the form of that name found fossil in the tertiary beds of Europe. The species were dredged up from depths varying from one to 100 fathoms. In the description of Amphidetus he gave an account of the spines of that genus, which he had discovered surrounding the ovarian foramina, and which are protected by cysticles formed of regular circles of spines. He gave an account of the habits of Cidaris histrix, which he had taken in 70 fathoms water, and which has the power of climbing up rocks by means of its spines alone, a fact not previously observed. The Echinus lividus is used as an article of food by the Greeks, and is identical with the Irish, which excavates rock-perforates rocks. The paper was illustrated by diagrams, and was read by the Professor himself.

GARDENERS' BENEVOLENT INSTITUTION.

January 11.—John Seagrim, Esq., in the chair. The report of the committee was read, by which it appeared that during the last twelve months 7 new and 4 annual pensioners on the funds, at 20*l.* per annum, had been given; also 17 annuitants, at 10*l.* per annum, had been elected on the list, the election to take place in May next; that four pensioners in 3 years, and two in 2000, resigned their pensions, amounting to 80*l.* per annum, to the Treasurer of the Institution, for the benefit of the funds of the Institution. W. and J. Keith, the Treasurers, in

12th inst. The report was carried unanimously. The meeting proceeded to the election of six pensioners, in room of those who go off by rotation, when the following were proposed and elected, viz.:—Messrs. Isaac Finchman, gardener to the Archbishop of Canterbury; James Thomson, Gentleman, Fanshawe-street; John Henderson, Nursery, Pine Apple-place; Hugh Low, Clapton; John Lee, Hammersmith; and John Murray, Strath Isla Cottage, Bow-road. The meeting then proceeded to the election of two pensioners, Mr. John Henderson in the chair. Messrs. A. Chandler and J. Saugster being scrutineers; when James Anderson, aged 72, and Ann Potter, aged 69, were severally elected. About 60 friends of the Society afterwards dined together, when the Secretary announced the following donations:—Messrs. W. and J. Noble, second donation of 10*l.* 10*s.*; Wrench and Sons, 10*l.* 10*s.*; George W. Norman, Esq., 10*l.* 10*s.*; Finlay Fraser, Esq., 10*l.* 10*s.*; Professor Lindley, 5*l.*, and a number of annual subscriptions and donations, amounting in all to 90*l.*

Rebietos.

Rivers's Descriptive Catalogue of Pears is a list of the varieties cultivated in the author's Nursery at Sawbridgeworth, with a brief account of their qualities, and some very useful practical instructions in root-pruning. Mr. Rivers's collection is one of the best in the country, and contains, what is unusual, all the best varieties grafted on Quince-stocks. There are also many kinds collected by him in France, unmentioned in the Horticultural Society's Catalogue, and said to deserve cultivation. This little pamphlet merits the attention of fruit-growers; we believe it is given to the author's customers.

Species Filicum; being Descriptions of all known Ferns; illustrated with Plates. By Sir W. J. Hooker, K.H. Part I. 8vo. Pamplin.

In these days, when men are beginning to appreciate the importance of Ferns, this book is most welcome. It is not merely the Geologist, who finds their value as a means of identifying the age of the rocks which he has to examine, nor the Botanist who sighs for some efficient means of classifying the heaps of these plants with which his herbarium is loaded, to whom such a work is acceptable. The Gardener who—in a small way by means of Ward's cases, and on a large scale in his damp stoves and greenhouses—is able to perceive the beauty of Ferns, will also think Sir W. Hooker's book a welcome addition to his library; for here he will find his favourites described, their technical characters canvassed, and the rarer species illustrated by excellent drawings on stone. A mere systematical work admits of no extract, we can therefore only recommend this to all who are interested in the matter, as a publication with which they cannot very well dispense. We only wish that we saw a probability of the fossil Ferns being examined critically and incorporated with the modern species.

GARDEN MEMORANDA.

The Fence, Macclesfield.—The Orchidaceous plants here are looking remarkably strong and healthy. The method of supplying moisture, which is described at p. 191 of last year's *Chronicle*, appears to answer the purpose exceedingly well. The plants are neatly arranged in various forms; some are growing in wire baskets and some are on wooden blocks, or rough bark, suspended from the roof; others, of a dwarf habit, are placed in collections upon large pyramidal blocks of wood neatly covered with bark and Moss. The majority of the finest plants, however, are placed upon inverted pots in leaden cisterns from two to three inches deep, which are always full of water. The heating apparatus is so constructed as to fill the house with steam (at any time when wanted) in less than five minutes; so that by this means, along with the vapour that arises from the water in the coolers, a moist growing heat is maintained. The temperature of the house is kept up to 75°, but 65° is considered to be sufficient for the growth of the greater part of Orchidaceous plants, although a few will succeed better in a higher temperature. There is a beautiful plant of Ipomœa Horsfallise trained along the roof; this is now covered with crimson flowers. Besides this, the following plants are now in bloom:—Gongora speciosa and G. maculata; Lælia albida and L. acuminata; also Dendrobium Calceolus, Bessia candata, Zygopetalum intermedium, Sophronitis coccinea, and Odontoglossum pulchellum, &c.—*F. M.*, Jan. 12.

Miscellaneous.

Improvements with regard to inducing Trees to form Roots, so as to render them independent of the Stock.—Mr. Rivers remarks that Pear-trees, more particularly those grafted on Quince and Apple trees, on Doucin and Paradise stocks, derive great benefit when roots are emitted above the graft,—particularly in soils that are unfavourable for the longevity of these trees. It therefore becomes desirable to assist or induce the formation of such roots artificially, as follows:—When a plantation of these trees is made, the graft should be from 2½ to 4½ inches below the surface of the soil. Two or three years after, in autumn, when the sap descends in greatest abundance, which is generally the case in July, the soil is removed, so as to expose the point of junction of the graft and stock, and immediately above this, several portions of the bark are removed, about [illegible] of an inch in width, and from [illegible] perpendicular [illegible] about [illegible] from each other, from [illegible] to [illegible] deep, that [illegible] and their [illegible] should, of course, be previously [illegible] to the [illegible] of the tree, but so that not more than one-fourth of the bark shall be removed. (Hence two incisions nearly half an inch in width, and an inch in length, would be removed at equal distances from a tree 8 inches in circumference.) The wounds must be immediately covered with rich soil. Two quarts of decomposed cow-dung, and six quarts of maiden-loam, well mixed, form a good compost for the roots to strike into in the first instance. It is to be regretted that this mode of invigorating the trees in our gardens and orchards has not been hitherto employed. Some that have struck root naturally from above the graft may be seen growing with remarkable vigour, whilst others adjoining, living only on the stock above which they form excrescences, languish during a short existence. This mode ought to be adopted for all grafted trees destined to live in a light hot soil.‖

Progress of Vegetation in the Spring and Summer of 1843.—M. Pépin remarks in the "Revue Horticole," that the spring of this year has been very favourable for the growth of hardy plants, more especially those growing in calcareous and sandy soils. The trees which had been planted in 1842, and which had suffered much from drought, pushed with great vigour, as did likewise those recently planted. In many instances the straw of Rye was twice the length it usually attains; and the same may be said of the stalks of Beans and haulm of Peas. The common Fox-glove, and the white variety of the same, were among the plants observed by M. Pépin as exhibiting remarkable luxuriance, their stems attaining the height of nearly 10 feet. The rains which fell so abundantly in May and June mainly contributed towards this state of vegetation. But, on the contrary, the cool and humid state of the weather was unfavourable for exotic vegetation, for it was remarked by amateurs and cultivators of ornamental plants, that such as were planted out from under glass, produced, in a lingering manner, very imperfect and badly expanded blooms.‖

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

Stove.—A few plants will now or soon begin to grow in large collections. Some time ago this used to be the first note of preparation for potting, but now few gardeners will pot or shift plants for the next six weeks. A good criterion for the time of spring potting any plant is, when the roots are observed to grow freely. It follows, therefore, that plants which are grown in bottom-heat will require shifting much sooner than those on shelves. Pruning, more or less, is necessary for almost all plants, and the time for this work is regulated by that when the plant is expected to flower. One gardener wishes a plant to flower in May—a second does not wish to have it in flower until July, while a third is endeavouring to keep the same plant from flowering until September. He who flowers his plants nearest their natural time will of course have the most success. Little water should be given during this month, and the house should be kept at a low temperature.

Conservatory.—Orange-trees that have been forced last spring, and kept in-doors all summer, will now begin to grow, and if they are in good condition they will flower freely on the young wood and little side-spurs. In order to get them into regular shapes, the strongest shoots ought to be stopped occasionally with the finger and thumb; not, however, until after the flowering is over. March is time enough to repot established plants of these, but young ones in small pots may be shifted now, and turned into bottom-heat in the forcing-pit. No plant delights in bottom-heat more than the Orange, and few plants which will live over the winter in a low temperature like it, will stand more stove-heat at all times when treated as a stove-plant. Another peculiarity noticed in the Orange is, that it requires less earth to grow in, to produce heavy crops of fruit, than any other plant of the same size; bad drainage and too large a pot would soon injure the best Orange-tree in the country. Avoid as much as possible letting in strong currents of cold air at this season, even when going in or out by the door; but in mild weather you may give air for several hours in the middle of the day. Water early in the day, and keep the plants constantly clean from dust or insects.

Greenhouse.—The grand point to attend to in this house is to keep the plants from growing till as late in the spring as possible; such plants as show a disposition to grow early should be removed to the coldest part of the house, or to cold frames in mild weather—anything rather than an early spring growth, unless for some special purpose. As fires are seldom wanted for drying up the house after this time, as little fire heat as possible should be used, and any covering at hand to throw over the glass in heavy weather will lessen the necessity for strong fires, which, besides the economy of saving coals, is much better for the health of the plants. Pelargoniums and Cinerarias require more heat than the woody greenhouse plants, and are kept in houses by themselves in nurseries and large establishments, but where there is only one house for the whole these may be kept in the warmest end.

Forcing Pits.—Randle's tanks are excellent contrivances for forced flowers; from 70° to 75°, or even 80°, of regular bottom-heat, day and night, may be kept up in the forcing-pits. The surface-heat may be regulated by ventilators, from 65° to 80°; but it may be allowed to rise a little higher by sun-heat; too much heat applied at first is sure to end in disappointment. Roses of all sorts do better when first brought into a temperature of 55°, with a bottom-heat of 75°, and not to pass 60° till all the eyes are fairly started. A dry atmosphere is best for very early forcing; we can always supply moisture as we think necessary. Recently-built pits, and especially where tanks are used, are troublesome for this branch of gardening, owing to the quantity of moisture they produce.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

Where any of the beds in the flower-garden require the soil to be renewed, frosty mornings offer an opportunity of doing the work cleanly and expeditiously. By far too little attention is paid to trenching and draining flower-beds; it is surprising how much better tender plants support the summer drought in beds that have been trenched than in those that have been merely dug.

Reserve Garden.—Any of the annuals that have been injured by the late frosts had better be cleared away, and if the ground between the plants can be stirred up on a dry day with a small hoe it will do them good. Wall-flowers, Sweet Williams, Hollyhocks, and any of the more hardy biennials, may be removed to the flower-borders. Wall-flowers, if for their fragrance only, should be planted abundantly in all gardens.

Pits and Frames.—Where there is the advantage of a little heat a sowing of Ten-week and Intermediate Stocks may be got in; and if strong plants of Calceolaria, Brachycome, &c., &c., are required for bedding out, they also may be sown. Should not another pot or two be sown this week, the most forward of the Verbenas, &c. in stock-pots may be potted off. Give them a little heat afterwards until they make fresh roots.—*W. Pitt.*

III.—FLORISTS' FLOWERS.

Auriculas will sometimes, at this season, show a truss of flowers (as remarked of the Polyanthus last week), which, of course, must be taken off. Should it happen to be what is termed "a heart bloom," some danger of losing the plant (in consequence of the stem decaying and rotting the centre), may take place, unless it is removed in a proper manner. The best way is merely to pluck off the pips without injuring the stem, by which means the danger is often avoided.

Polyanthuses.—Mice will often attack these plants at this time of the year, especially when in frames, and commit such ravages by eating out the hearts, and it will require some vigilance on the part of the grower to prevent them. Snails and slugs are also great pests to both Auriculas and Polyanthuses. A little fresh bran, placed under a flat tile, raised at each corner by small pebbles, I find to be the best trap amongst the many recommended.

Ranunculus growers are beginning to be on the *qui vive*; their necessary additions to the bed bed ought now to be made, by purchase or otherwise. The names of a few excellent varieties will be given next week. Raising these beautiful flowers from seed is much better understood now than formerly, (thanks to Messrs. Tyso, Lightbody, and others), many of the old varieties being eclipsed by superb sorts of their raising.

Carnations.—The purchase of these favourite flowers, if not already done, had better be deferred till planting time.

Tulips must still be assiduously cared for, on frosty nights, by covering as before alluded to. A lattice round the outside of the frame is a great protection, especially when they are further advanced. Last season I was much delighted with a trellis of this description; it was covered with the best varieties of Chinese and Bourbon Roses, thus giving fresh interest to that part of the garden when the Tulips were out of bloom.

Pinks.—We may expect frost and snow, and where gardens are exposed to the incursion of hares and rabbits, Pinks as well as Carnations stand but a poor chance when the ground is covered, as they will scratch away the snow to obtain access to them. A net made of tarred-twine will be found an effectual preventive, when stretched to about seven feet from the bed.—*J. F. M.*

IV.—PINERIES, VINERIES, &c.

Pinery.—Where a regular supply of fruit is required, there will, about this time, be some of the plants in the fruiting state showing, and if the bottom-heat is obtained by hot-water tanks, these may be turned out of their pots and planted carefully in the tan over the tanks, with six or eight inches of soil all round the roots, and put well up about the collar of the plant. If this is carefully done, and the roots of the plants are healthy, the fruit will be finer fruit and stronger suckers. Do not yet increase the heat if you can avoid it. If sometimes is necessary to hasten the fruiting of some of the plants, but in this case, remove those most likely to fruit to another pit, if you can, rather than subject the whole to the high temperature, for the present. Look frequently over the whole of the Pines in pots, to see that none are too dry from the heat of the pipes or flues.

Vinery.—Many will now be about to start their first house of Vines, and it should be well considered, before putting any heating material over the outside border, whether a proper supply can be conveniently obtained to keep the heat regular. It must be cautious to avoid laying on so much fermenting material at first as to cause much heat, and then to let it decline for want of fresh material. On the other hand, where a sufficient quantity is always at command, and the heat is kept regular, by frequent stirring and adding fresh dung as required, it will prove very beneficial to the Vines. If the material over the border can be kept dry it will be better. Where the Vines are showing fruit the shoots demand constant attention; let the leading ones grow until the desired length of rod is obtained; stop all others; tie the fruit bearing spurs down to the wires, right and left of the rafters, to keep the leaves from coming in contact with the glass. Leave only one bunch upon each spur. If the sorts are the Black Hamburgh, White Muscadine, or other hardy kinds, a temperature of 60° by night will be high enough, with a rise of 10° by day. During sunshine admit a small portion of air, when the thermometer reaches 80°, letting it rise to 87° or 90° before it is given.

Peach House.—It may be useful to many to know that applying the pollen to the stigma of the Peach-blossoms here, by means of a camel-hair pencil as recommended in the Calendar of a former Number, has succeeded perfectly, although out of twelve trees only three had the pollen good. Disbudding should commence when the trees are out of bloom, removing a few at intervals of three or four days. It is better not to make the shoots too rank during the summer. Leave those shoots situated at the bottom of last year's wood to keep the bearing-wood regular over the tree. Syringe freely in the morning and evening; and if green fly is observed upon the trees, or in the house on other plants, fumigate with tobacco.

Fig House.—A good way of treating Figs in pots is to plunge them in a row upon the floor of a Fig-house at work, or Vinery, and place leaves and tan round the pots in the form of a ridge. It will produce a mild heat, and keep the roots in a more uniform state, both with regard to moisture and heat, than if exposed to the atmosphere of the house.

Strawberries.—It often occurs, that in attempting to get a very early crop of Strawberries, they are subjected to too much heat, and kept too close, and failure is the consequence. They should be kept cool at first, and have plenty of air daily, except during frost or cutting winds. They should on no account be subjected to the same treatment with regard to heat and air as Vines and Peaches are is often done, till after the fruit is set, when they will do well in the Vinery or Peach house shelves.

Melons.—The plants for the early crop will, with some, be ripe and when about 3 inches high should be potted off into 32-sized pots, one in a pot, and plunged in the bed in the frame near the glass. Sow a few more seeds, in case of failure. Keep up a steady heat of about 70° in the bed by adding fresh linings, or if the heat is supplied by pipes or tanks, which is much better, 60° by night will do, with a rise of 5° to 10° by day. Of course those who have a Vinery at work, or a heated pit for any purpose, will raise their first Melon-plants in these, instead of making either a bed for them or heating the Melon pit, till the plants are fit to turn out.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Gooseberries and Currants, if pruned, may now be washed over with a mixture of cowdung, soot, soot, and lime, mixed with water to the consistence of thick paint.

Plums and Cherries will be benefited by washing with a similar mixture, adding to it, if thought necessary, Tobacco-water and flowers of sulphur.

Planting of Fruit Trees, where it is not finished, should be deferred a month or six week longer; meantime prepare the ground for their reception. In this changeable weather, much care is required for forward vegetable crops.

Sea Kale and Rhubarb will be most economically obtained at this period by taking them up and planting them thickly in a slight hotbed. Fresh plants will be required every season.

Asparagus.—To keep up a succession, fresh beds will require to be started every three weeks. A temperature for the roots of 65° is most desirable. When fresh beds are made and there is danger of over-heating, it is advisable to have some rows of drain-tiles across the bed, by opening the ends of which the superabundant heat will escape. They will also be useful in diffusing the heat of a lining when necessary.

Radish and Horn Carrots.—Slight hotbeds should be got ready for crops to succeed those now coming into use.

Mustard and Cress.—Sow these once a week in a little heat; the soft tan recently be too dry. For all these purposes much fermenting material is necessary, but there is always a quantity of refuse from the flower-garden as well as the kitchen-garden, which instead of being taken to the rot heap, ought to be made available in the frame ground.

Mushrooms.—I am obliged by the statements of "*J. C.*" and a "Mushroom." It is, however, often very difficult to assign a reason for failures. "*J. C.*" states, "that for some time past a kind of fungus matter, having the peculiar appearance of a cobweb, spreads over the bed, and completely rots all the fruit it comes in contact with; and that changing of the soil and the skin of the bed, has been attended with no benefit." Something similar happened here last season. I attributed it to damp, and having swept it clean off the bed, and introduced a stream of air, I saw no more of it. As "*J. C.*'s" beds are out of doors, open hurdles or Fern-stalks put on the beds before they are covered up might be of advantage, especially if on a mild day openings were made in the covering, so as to permit the air to circulate between the hurdles and the bed. As it is likely that "J. C." from being an extensive grower makes his own spawn, it would also be advisable to obtain good spawn from another place, to supersede what he may make in future. A "Mushroom" states that his Mushrooms "appear above the soil, and then die off, turn brown, and that many small worms are in the soil." This failure will sometimes happen from these causes:—Watering the crop overhead and exposing them to a cold atmosphere; using unheated old soil, or that which is stuffed with vegetable and animal matter, worms, &c.; all which prevent the surface of the bed from being solid and smooth; keeping the surface of the bed damp, while it is very dry underneath; and perhaps chiefly from spawning the bed a considerable time before it is earthed up, by which means the spawn is apt to exhaust itself so much on the damp as to prevent it penetrating the soil in a vigorous state.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—In old woods seedling plants of timber-trees often spring up, but are destroyed for want of relieving, by being pressed down by snow, or by being smothered with Ferns or briers; the overgrowth of other plants also renders them of comparatively little value. A person accustomed to such work would be beneficially employed in going through the woods at this season to relieve these from their oppressing neighbours; they might be raised and fastened upright by various simple contrivances, which I cannot at present point out. They should be kept to one leader. If there are two or more leading shoots of nearly equal strength, cut close off, or shorten the least promising one; also shorten some of the lower longest side-branches to about two or three feet from the stem, according to the size of the plant. Thousands of maiden plants might be preserved by this simple and cheap method. I have saved many a plant from destruction by these means; but be sure to reserve as many side branches as possible of a moderate size, till the plants have become *stocky* (strong) and able to support themselves.

Coppice.—Considerable benefit would ensue, and great increase of growth would be derived, by following the directions here, as in Old Woods, viz., by employing a person to go over the Coppice in the winter or spring months, if they have not been done in the summer. Select a proper number of the strongest and best shoots from the stools, seedling plants, or suckers, for future purposes, and shorten the strongest lateral or side-branches of them, or cut any of equal strength with the leader close off, but by no means divest them of the moderately weak laterals; nor would you cut out the weak ones, only prune off their heads to prevent them growing up to injure the reserved poles, rods, &c.

Young Plantations.—When thinning in groups or otherwise, as advised in the last No., and where a permanent undergrowth is desired, as a blind or for shelter, particularly in narrow belts or small plantations, instead of cutting clean out any that are required for the good of the permanent trees, I would only prune off the heads of some of the inferior kinds, cutting them off to a side branch or branches—say from the height of from three to five or six feet, particularly on the side of the plantation most exposed to the wind. Beech and Hornbeam may be so done as they retain their dead leaves in winter; Silver and Spruce Firs also are suitable for this purpose, but not the Scotch Fir, except for the outsides of the plantation. Hollies, if any, should be kept down in like manner, and Whins or Furze when young; afterwards the spade should be employed to destroy the Whins. By this method a permanent undergrowth may be secured for a long time. Where it is not designed for Coppice you need not stop to trim the lower tier of branches off the permanent trees, as recommended by some, at regular intervals; *Nature* will do that as the trees get up; nor need you be afraid of exhaustion of nourishment to the roots, by having a superabundance of them; only give them *light* and *room* in moderate compass, with regulation of branches, and you may safely leave most kinds to Nature for a time.

Hedge-rows and Nursery Work.—There will not be space this week to say much under these heads, or I had intended to describe the means I use with success to preserve young Apple or other trees from the depredations of hares and rabbits. I must defer it to another time, and as the weather continues open they will not do much damage.—*W. B.*

State of the Weather near London for the week ending Jan. 13, 1844, as observed at the Horticultural Garden, Chiswick.

Jan. 13. Rainy; constant rain throughout the day and night.
14. Slight drizzle; heavy clouds; equally, and at intervals quite calm, with slight rain at night.
15. Misty and drizzly; fine, with strata of light and dark clouds; densely overcast.
16. Clear and frosty; cloudy and cold; clear and frosty.
17. Hoar frost; fine, with bright sun; densely overcast.
18. Slightly overcast; cloudy; overcast at night.
19. Overcast; cloudy and gentle throughout, densely overcast at night.
Mean temperature of the week 3° below the average.

State of the Weather at Chiswick during the last 18 years, for the ensuing Week ending January 27, 1844.

Date.	Aver. Highest Temp.	Aver. Lowest Temp.	Mean Temp.	No. of Years in which it Rained.	Greatest quantity of Rain.	Prevailing Winds.

The highest temperature during the above period occurred on the 23rd, 1834—thermometer 59°; and the lowest on the 27th, 1837—thermometer 17°.

Notices to Correspondents.

Communications from the following Correspondents are in type, and are only waiting till room can be found for them:—*Dr. Lindley, T. Berry, J. Salisby, W. G., I. W. K., Vitis, J. Bland, Brighton, G. Thompson, Bamboo, A. Dunstan, A Practical Gardener, F. Mackenzie, Or., W. Billington, G. Fleming.*

Hot-water Apparatus.—*E. S. L.*—We believe this to be a very good kind of temporary covering, and one that will with care last a long while.

A great Small Gardener.—There is no cheap machine known of for crushing bones. Your only way is to break them with a sledge-hammer, and dig them into your borders. We have not forgotten our promise about Fig, but it is not easy to find a good one.

Books.—*W. S.*—Newman's "History of British Ferns" will possibly suit you.——*A Friend to the Needy.*—Raddi's book on Brazilian Ferns may be had through the Italian booksellers. No other has been published. The other questions are beyond our limits.

Broccoli.—*W. M. R.*—"Shooting flower" in the Calendar means when the plants begin to show their heads, and therefore your plants that are not likely to do this before April, cannot be safely removed in the way there directed.

Canker in Fruit-trees.—*Abbotsgrange.*—Similar instances of Canker to that exhibited by the shoots of your Pear and Apple-trees are too frequently to be met with. It is the same disease both in the Apple and Pear-tree. Some varieties are more subject to it than others, and in some soils it is induced on almost every variety planted in such. Wood that is produced in cold wet seasons is apt to canker in succeeding years. If it be owing to the variety, this may be easily changed; if the soil be the cause, endeavours must be made to make it better. Lime will probably do good. Shoots produced in a bad summer should be well shortened in.

Conifers.—*A Nurseryman.*—Cones of the Deodar cannot be had in this country at all; they must be procured from the East Indies. So also, in general, must the cones of rare Pines be had from their native countries. The Deodar will take on the Larch; grafting must be performed while the wood is soft.

Conservatories.—*A Subscriber of* 1843.—A conservatory, properly so called, is a place in which plants are preserved during winter without being forced. In such a building the thermometer may fall as low as 35°; but it is better to keep it to 40° as a minimum, if possible. Even a few degrees of actual frost will not harm hard-wooded conservatory plants, but it is better to avoid the risk.

Forced Peaches.—*Inquirer* sends "a few defective blossoms of Peaches and Nectarines, of which he wishes to know the cause, and how to remedy it. The defect consists in a total or partial absence of the female part of fructification. The trees are in a favourable condition as respects strength of wood, which was well ripened. The fruit last season was ripe in June and July. The trees were attended to, by syringing, &c., but the sashes were not completely removed, though plenty of air was given. The border lies low, and cannot be raised, but was defended from wet early in the autumn. It is now defended from cold, and is in a favourable condition as respects moisture. The house is not favourably constructed, but though it requires more care after the crop is more forward, I do not think it could have any influence upon the blossom. The trees have been brought on very gently; the temperature ranging from 45° to 55° at night, according to the weather, and about 10° higher during the day. Some trees in the house have scarcely any defective blossoms, others are quite the reverse; the same treatment has been given to all. The oldest and most valuable tree is the worst, though the blossoms on it are so thin that the greater part of them would be required for a crop. The wood is in a good heavy condition." [We find all the blossoms sent us to be males—a very singular circumstance, for which we are unable to account. Can any of our physiological friends assist us?]

Garden Walls.—*A Subscriber.*—We are not aware of any reason why a wall built in cement should not be as good as one constructed with mortar; especially if copper wire is used for fastening the branches.

Heating.—*Anonymous.*—Hot-water is a much better heating material than hot air in flues. The cheapest boiler you could get would be the best, for all that are now manufactured are sufficiently good for so small a house as yours. If you use pipes employ those four inches in diameter. One row above the other will be enough, and the nearer the floor the better. But you will probably find it worth your while to use iron troughs instead of pipes. We never give prices; for them you must apply to the advertisers, of whom many are to be found in our columns.——*Inquirer.*—It appears that you have 270 feet of four-inch pipes, heated by one small saddle-backed boiler, placed 30 feet from your pits, and communicating with them by means of a main pipe buried in earth. If this is so, your enormous loss of heat and the impossibility of obtaining warmth, with even an expenditure of one ton and a half of coals per week, are accounted for. If the pipe that connects the boiler with the pits were carefully inclosed in a well-constructed tunnel, there would be no great loss of heat. But it is far better that the boiler should join the pits; even then 270 feet of four-inch pipe are more than a small saddle-backed boiler will heat. In all probability, both the boiler and its situation require changing. In such a case you will find the advice of a *skilful* architect by far the cheapest purchase you can make before beginning alterations.

Heraldic Gardening.—*J. D.*—It takes more time than we can possibly spare to answer questions relating to this subject; and moreover, answers are of little use in matters where much depends on climate, soil, and the means at a man's disposal. Nothing, in fact, is more difficult than to do well that which you are required to effect. If we understand you, no flowers will do except what are easily procured, easily propagated, totally hardy, dwarf, and capable of flowering in succession for some time. Your family shield is cut out in Grass, and must be constantly filled, spring, summer, and autumn. The device is 3 bars wavy gules, on a field or, with an escallop argent in the middle of each bar. The following may be kept dwarf by pegging and topping, or are so naturally; but they must be grown in pots, so that they may be planted when in bloom:—

[For the Field Ob.]

Spring.	*Summer.*	*Autumn.*
Yellow Crocus	Dbl. Yellow Wallflower	Œnothera macrocar.
Double Jonquil	Shby. Yel. Calceolaria	Shrubby Calceolaria
Adonis vernalis	Chrysocis crocea	Chrysocis
Alyssum saxatile	Yellow Heartsease	Sphenogyne speciosa

[For the Bar Gules.]

Spring.	*Summer.*	*Autumn.*
Dbl. Red Hepatica	Verbenas	Verbenas
Red Anemone	Frogmore Geraniums	Geraniums
Red Hyacinth	Scarl. Ten-week Stock	Pentst. gentianoides.
Arabis rosea	Clarkia pulchella	Dwarf Fuchsias.

[For the Escallop Argent.]

Spring.	*Summer.*	*Autumn.*
Snowdrops	White Candy Tuft	White Verbenas
White Hyacinths	White Clarkia	White Petunias
White Crocus	White Nemophila	White Œnotheras
Arabis grandiflora	The Queen Verbena	Oxeye Daisy

Hotbeds.—*Suffolk.*—Small as your hotbed is we cannot advise you to heat it with hot water. You will have too much power for a very little work. It is hardly possible to get a boiler small enough not to be too powerful. It will be better to make up a good foundation, three feet high, of old roots and refuse wood, secured by four stout stakes at the angles, and to obtain your heat from hot dung and leaves mixed. For a larger pit your arrangements are good, except that two inches of water-way are not sufficient; four inches would be better.

Insects.—*W. W. E.*—The bodies on the Oak-leaves are Cladapangica, described at p. 32, 1843. The other appearance on the branches of the Fir, produced by an Aphis, has also been mentioned at p. 805, 1843.——*An Inquirer's Constant* will produce in the spring a Beetle called Tentheredo (Cimbicoidea) Liliorum of Linnæus. *R.*——*Northumbrensis* having found specimens of an Aphis amongst the leaves of the Rose fragrans, I conclude that is the insect which causes the stalling of the leaves. If such be the case, fumigating with Tobacco will be the best remedy. *R.*——*L. J. P.*——[illegible] is a Bombyx, whose history begins in the December number, Vol. II. p. 788; but the specimens having been destroyed from not being preserved in a quill, it is impossible to determine the species. We will attend to the suggestions respecting the House-flies.—*R.*

Laburnum.—*Corrup.*—For a narrow belt, upon a chalky soil, &c., the Laburnum cannot recommend the Larch to *J.*, as it is not unfrequently under such circumstances to place him, either by its timber or its ornamental qualities. Beech, a few Oak, and Birch, are more likely to answer his expectations. These must be kept well thinned from an early period of their growth. If the Larch is wanted for shelter, or as a screen, a thick undergrowth of Thorn, Bird-cherry, Holly, Laurels, &c., should be put in at the same time with the Forest trees.

Maclura aurantiaca.—*J. W.*—This plant seldom blooms until it is very old. If it is growing vigorously, stopping the leading shoots in spring, so as to encourage laterals, might possibly induce it to form flower-buds. It succeeds best in a rather poor soil, as where this is rich the plant becomes too luxuriant to bloom freely. Your plant of Camellia japonica, that was in a sickly state from being too long in a drawing-room, but upon being shifted had recovered and made healthy young shoots, is the result of the good treatment you have given it, and is only what might have been expected.

Mildness of the Season.—We thank our correspondents for their continued communications on this subject; but we think it hardly desirable to publish further details at present. Just us see what happens in February.

Myrtles, &c.—*A Reader.*—We are not aware of an easier or better way of cleaning Myrtles and Oleanders of insects, than by washing them with water and a sponge. Camellias may be plentifully supplied with water when they are coming into bloom, if the drainage is perfect; but too much water, as well as too little, will cause the buds to drop; an important drainage is often the cause of the buds dropping. A remedy for the club in Cabbages is given at p. 828 of the vol. for 1843.

Names of Plants.—*S. W.*—Your packet is addressed to the Post-office, Bishops Waltham, you having forgotten to give your address.——*A Young Gardener.*—1, Quercus Ilex; 2, Phillyrea latifolia; 3, Quercus Ballota; 4, Tinus orientalis; 5, Jasminum revolutum; 6, Rhamnus alaternus, gold-blotched; 7, Phillyrea obliqua.——*J. C. L.*—Hexadesmia fasciculata. The plants will be sent when the frosts are over.——*C. D.*—As far as we can guess from the drawings—1, Orobanche cærulea; 2, Lactuca saligna; 3, Azalea procumbens. You will find Koch's "Flora Germanica" an excellent book for European plants. If you cut out the news part of the *Chronicle* you will have the same quantity of matter left as has been hitherto furnished. It is hardly possible for the news-agents to fold it properly. *Everyone should damp it and refold it himself*, when he will find that the pages are very carefully arranged for future binding.——*Orwell Park.*—Your Hippeastra are to all appearance hybrids, for which no recognised names have been given. 1 is nearly the pure pulverulentum; 2 is probably a cross between that species and reticulatum or Johnsoni.——*Wyeside.*—Clavaria muscoides, Hypnum proliferum, Marchantia polymorpha.——*Philanthus.*—Borrera ciliaris.——*A Lady.*—Elymus arenarius.——*E. R.*—Camellia maliflora.

Oaks.—*Acacia.*—It was the Quercus sessiliflora, advertised by Mr. Rogers, of Southampton, that we recommended; at least, we imagine that to be what you are inquiring for.

Passion-flowers.—*J. C.*—The hardiest Passion-flowers are the following—Passiflora cærulea, Colvilii, Mayana, and incarnata—but they are apt to get injured if planted in the open air, even in tolerably mild winters, and particularly if the situation is not a very dry one. They strike readily from the slenderer shoots after Midsummer, if the wood is a little hard. The cuttings should be put into white sand, covered with a bell-glass, and placed where there is a good bottom-heat (either in a dung frame or hot-water pit). When struck they should be potted singly into small pots, and returned for a few days to the frame or pit; afterwards harden them off by degrees.

Payment of Rent.—*Notice to Quit.*—*G. W. T.*—If the premises were let at the rent of 10*l.* a year, and no mention was made as to when the rent should be paid, the landlord cannot demand any part of it till the end of the year. If the tenancy commenced at Midsummer the notice to quit must expire at that time of the year, in the absence of any express stipulation to the contrary, and the notice to quit in March is invalid.

Pelargoniums.—*J. R.*—Two or three of the flowers in your list we have not seen; but the four first put down, although not answering completely to the qualities mentioned, will please, from their novelty and goodness.

Picotees.—*J. C.*—There is no particular names for the hardy border Picotees. They are generally raised from seed, and any florist can furnish the old double kinds of border Carnations. One of the best is Cuthill's Nosegay, or Prince Albert.

Temperature.—*S. A. S.*—The thermometers made by Mr. Newman for registering the temperature in the Horticultural Society's Garden at Chiswick are quite correct. There is frequently as much as 10° difference between the minimum as observed in London and Chiswick at night. On the night of the 2nd, or morning of the 3rd inst., to which you particularly allude, the temperature indicated by thermometers in the Society's Garden and by others in Chiswick was 14°; at Rochester, 18°; at Thwaite, Suffolk, 24°; Walworth, 19°; Brighton, 26°; and at Uckfield, Sussex, 11°; whilst with you, in London, it was 20°.

Miscellaneous.—*Iris.*—We are sorry we cannot help you to get lamp-oil out of paper.——*Priapus.*—The price of flower-pots varies with the makers and local circumstances—as, for example, the distance they have to be carted.——*A Constant Reader's* request is unreasonable. We cannot fill our columns continually with lists of plants which it is desirable to buy. Many such lists have already been given in former Numbers which can be consulted.——*Didymus.*—We always print the Proceedings of the Hot. Society when they are sent us by the Secretary. We cannot obtain them through any other channel.——*O. P. I.*—You may fill your Melon and Cucumber pit up over the flues with rough gravel or brickbats until within two feet of the glass. Over this it will be necessary to put a layer of turf, in order to prevent the soil from getting down among the bricks; this material will answer the purpose better than rough dung, which you are anxious to save, as the dung creates an impure atmosphere, which is apt to injure the plants at this season, when very little fresh air can be admitted. The temperature of the pit may be kept at from 65° to 70°, the front and back part over the flues should be watered, to keep up a moist atmosphere. Spanish Broom may be increased either from seeds or by layers. Your Cacti in a greenhouse should be kept dry until they begin to show their flower-buds, when water may be more liberally supplied. In order to have them in flower by the end of March or the beginning of April, they should be removed early in February to some place where they would have a higher temperature than that of a greenhouse. If your Vines are weak they may be cut down to three eyes; but if strong, leave six or seven, and allow the top shoot to run up the rafters. If the weather keep mild your Verbenas may possibly survive the winter in a bed in the flower-garden; they must be closely covered up in frosty weather, with spruce branches or some other protecting material. The usual way is to strike cuttings of them in autumn, and keep them in a pit or on a shelf in the greenhouse till spring. We have answered these questions, but we cannot be supposed to [illegible] ments of their [illegible]——*W. D.* will find [illegible] making observations given in detail at p. 24, vol. [illegible] gati.——You may now prune any of the evergreens you [illegible] [illegible] [illegible]

[illegible]
AN INQUIRY into the NATURE of the SEVERAL [illegible] of AGRICULTURE. By JOHN LOUDON MACADAM, Esq., F.G.S.E. [illegible] of Agriculture in the University of Edinburgh.
Also, by Professor Low,
ELEMENTS of PRACTICAL AGRICULTURE. Fourth Edition, greatly improved, with 300 Woodcuts, 21s. cloth.

London: Longman, Brown, Green, and Longmans.

The Agricultural Gazette.

SATURDAY, JANUARY 20, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Jan. 31 } Agric. Imp. Society of Ireland . 8 P M
Thursday, Feb. 1 }

THE question, What is the PROPER SEED-TIME FOR WHEAT? is one which every district must answer for itself. It is only by experience that the habits of our cultivated plants can be ascertained; and this experience, in reference to Wheat, will doubtless vary with the climate and soil on which it is to be grown. On early soils in high-land districts, an earlier seed time is required than where the soil is early and the climate mild.

An experienced farmer of our acquaintance informs us, and our own experience for the last three or four years bears him out in the assertion, that in the mid-land counties of England, where the soil is dry, it is immaterial with many kinds of Wheat at what period between October and February they are sown. The productiveness, however, of some of the old varieties, which have received one unvarying treatment from time immemorial, would probably suffer were this treatment to be rudely altered. The habits of an autumn-sown variety, such as the Red Lammas for instance, which has hardly ever been sown in spring, must have grown upon it so perfectly, that any abrupt attempt to act in opposition to them would probably prove injurious. But there are some kinds which we have sown indiscriminately, at any time during the period alluded to, and even so late as the month of March, with results evidently unaffected by the variableness of this treatment. We have had from the Hopetoun Wheat, and from a sort named, on account of its peculiarity, the Red-straw White Wheat, a produce per acre from seed sown during every month in winter and spring, varying, from four to six quarters, altogether independently of the time when it was planted.

The proper time for sowing Wheat is thus the subject of a purely practical question, and we are not aware of any doctrine of vegetable physiologists which can assist in its solution. A preference is, however, given by the gentleman to whom we have alluded above, to one period in the season of Wheat sowing, as being the proper seed-time for all varieties, and he gives a very curious reason for his opinion. The period referred to lasts during the few weeks immediately preceding the frosts of winter, and thus, of course, his opinion can only apply to land which is naturally or artificially dry. He considers it right that the Wheat-plant should not appear above ground before winter, but that the seed should be placed in such a position as will enable it to take immediate advantage of the earliest signs of approaching spring. He grounds this opinion, we know not with what justice, upon the analogy existing between plants and animals; knowing well, that if in feeding a bullock the farmer allows its progress to be checked by negligence, or any other cause, he will suffer not only by the loss of all the food necessary to bring it up to the mark again, but also by the diminished aptitude of the animal to fatten, he considers that the early-sown and forward Wheat-plant, when checked by the frost of winter, not only has the organs injured by which it gathers food from air and soil, but that its capability also is diminished of remedying this injury by a future vigorous growth. Whether this idea be corroborated by the doctrines of vegetable physiologists or not, it is one which deserves our attention, for it is the result of a lengthened experience.

In one of his Lectures lately delivered before the English Agricultural Society, Professor Brande informed us that the efficiency of manures is often owing to certain mineral matters, contained in them only in minute quantities. Considering the expenses of carting, &c. which attend the use of our bulky manures, it is worth our while inquiring into this statement, for it is certainly one the truth of which is desirable.

The conclusiveness of an argument often depends upon the preconceptions of the persons to whom it is addressed; and we must therefore first attempt to show, that however unlikely the above statement may be to [illegible] have grown out of dealing with manures by [illegible] it is one which [illegible] proves to be [illegible] [illegible] it has been found that the [illegible] [illegible] perhaps, first [illegible] [illegible] [illegible]

profitable on farms that were difficult of access, and where the land had been completely worn out.

ON THE AGRICULTURAL VALUE OF LAND.

It is the quantity and value of its *free* produce which determines the value of land. We have nothing, however, to do with the latter of these particulars, for those circumstances which affect the demand for, and the price of, Agricultural produce have evidently no connection with facts affecting the amount which the soil is capable of yielding. When speaking, therefore, of the value of land, the quantity and quality only of the free produce it yields is referred to. Free produce is that which remains after the expense of producing has been deducted from the gross produce. The weight of crop which soil of any description is capable of yielding depends upon its capability of supplying food and nourishment in a manner and quantity suited to the nature of the plant cultivated. The degree in which it possesses this property is due, partly to its mineral composition, and partly to the nature and quantity of the animal and vegetable matters it contains; the former being the vehicle of nourishment to the plant, and the latter, together with some of the mineral ingredients, also constituting the nourishment supplied. Now, since the great majority of soils are owing to the disintegration of the rocks on which they rest, that portion of the value of land which depends on the mineral composition of the soil must be due to, and will vary with, the geological character of the district; and since the amount of animal and vegetable matter contained in the soil is chiefly owing to the cultivation it may have received from the farmer, that portion of the value which depends on the quantity of these matters which the soil contains must be due to, and will vary with, the treatment it has received.

Besides these, however, the effects of climate—a third and important item in the account—are to be considered; a difference in climate will make all the difference between a soil of the greatest, and one of the least value, in two cases which are otherwise under precisely similar circumstances; and as a difference in elevation produces such great changes in the climate of even a moderately extensive district, it is of importance, in the valuation of land, to know accurately its level above that of the sea.

If, however, for the present, we put this out of consideration, the value of land may be said to depend on two things—the nature of the rock on which it lies, and the treatment it has received from the farmer. Were it otherwise, and did the value of land depend wholly on its mineral composition, as due to the rock on which it lies, then a geological map of any district, and one on which the extent of the various descriptions of soil occurring in that district were laid down and defined, would consist of exactly the same divisions of the country, and in crossing the line dividing one geological formation from another, we should just be stepping from land of one kind and value, on to land of another kind and value. This, however, is not the case; but it is evident that it will be the more nearly true in the proportion in which land is in its natural state, for the less cultivated any district may be, the less will the value of its land be owing to any treatment good or bad which it may have received, and the more entirely will it be dependent on its mineral composition. In instituting a comparison, therefore, with respect to fertility, between the soils of any two geological formations, it would be incorrect to fix on highly cultivated spots, which owe their value chiefly to the good treatment of the farmer. Commons and waste land, on the contrary, are to be considered as affording almost the only true index of the unassisted fertility of any geological formation.

I.—The value of land depends in a great measure on its mineral composition.

All the mechanical properties of a soil are due to its mineral composition. It is heavy or light, and thus adapted for the growth of one plant or another, according to the prevalence in it of this or that earth. The mechanical properties of a soil are of the greatest importance. The slightest variations in them produce great differences, not only in the value and amount of the crop yielded, but also in the expense and difficulty of cultivation. The greatest care ought, therefore, to be taken to improve their properties. This can be *permanently* effected in two ways. The first of these is by drainage.

If the subsoil consist of sandy and clayey beds alternating with one another, the soil lying on it will be full of springs; if it consist merely of clay, the water falling on it cannot sink, but remains on the surface, where as long as it remains it renders every attempt at cultivation injurious instead of beneficial. In both of these cases the injury done to the land is of two kinds. In the first place, as long as a soil is wet, any treading which it undergoes in cultivation has the effect of kneading it into a mortar, which, on drying, becomes so hard that it will not allow the roots of plants to pierce it. The consequence is that the plant cultivated or the seed sown, after being half drowned or perished in the water, is withered in the sun. In the second place, as long as the soil is wet, the water, filling all the pores of the soil, hinders the admission of air, without which the decomposition of manure in the soil, necessary to the life of the plant, cannot proceed. These two modes, in which land is injured by stagnant water, render any means of depriving it of this water doubly valuable, and hence the immense improvements effected by drainage, especially when assisted by the new soil plough.—*M. S.*

(To be continued.)

AGRICULTURE OF THE ISLE OF MAN.—No. I.

[The subjoined sketch of Manx Agriculture is contributed in the hope that some industrious young farmers of moderate capital may be induced by it to visit the Island; and that, finding their ideas of Colonial emigration a little anticipated, they may be induced to settle there, and enjoy near home, freedom from taxes, poor's rates, and turnpikes, without incurring the hazard of a long voyage in search of it, to uncleared woods, unwatered pastures, and fickle if not sickly climates.]

As might be expected from its geographical and insular position the climate of this island is humid and variable, the extremes of heat and cold are little felt, so that neither is the progress of the plough much impeded by frost, nor the harvest materially injured by parching drought. To the practical farmer it will be hardly necessary to explain that on this account although the "course" of cultivation comprises the regular rotation of green crop and grain crop (of all kinds) yet Nature favours the former rather than the latter, and it is to the perseverance and industry which the Manx farmer bestows on his green crop, that he is indebted, under Providence, to the moderate and varying success which attends his grain harvest.

The island is divided into 17 parishes, all of which touch upon the sea, with the exception of the inland parish of Kirk-Maroun. The regular and, though speculative, yet at times remunerative employment of the Manx fisheries (the most prolific perhaps in the British seas) has for centuries drawn away the lower-born islander from the quiet pursuits of the farm, and that, too, at a time when his attention is the most required—in the hay and corn harvests. The most important operations are therefore confided to the female members of the family (for every father and father's son able to haul a rope or trail a net must needs go a-fishing) and right trustily do the Manx women fulfil their delegated trust; nowhere can be found women of more enduring industry. It may be safely averred that without the hearty and cheerful assistance of the Manx women Potatoes could not be planted nor the grain harvested, although, without doubt, herrings would be caught, and bloaters dried to perfection. It is, indeed, hardly matter of surprise that, with a varying climate, an ill-drained soil, with capital deficient, and energy not superabundant, while as stated in the clause introduced by Bishop Wilson into the Manx Litany, "the blessings of the sea are restored and continued to them" so abundantly, the islanders should prefer the less laborious and more stirring avocations of the ocean, to the steady returns of field-labour. At present, however, a brighter era appears to dawn over the interests of Agriculture in the Isle of Man, and this may be attributed to many causes. Wholesome and necessary laws have rendered the once splendid pursuit of the smuggler profitless and too perilous. The fisheries have been intruded upon by strangers, and the example set by wealthy Manxmen and resident strangers has excited profitable emulation; added to these the adjacent markets of Liverpool and Whitehaven have opened channels for the exportation of produce, and thus increased attention has been directed to the means of raising it, so that Mona promises soon to occupy a prominent place in the statistics of British Agriculture.—*Cultor.*

(To be continued.)

AGRICULTURAL EXPERIMENTS.

(Concluded from p. 26.)

Let me now solicit your attention for a short time to another experiment not unworthy the farmer's notice. I had seen a statement in the "Farmers' Magazine" that tailing Wheat, or Chickenscraps, as the farmers call them, because they are considered fit for nothing but to be food for chickens—being, in fact, the refuse of the Corn, will yet produce as good a crop as the heaviest, fullest seed. This seemed to me the strangest of all paradoxes, and I utterly disbelieved it; but yet I resolved to make the trial, because if it proved as I expected, to be false, it was desirable to undeceive the farmers, who might be deluded by it into the loss of their crops; on the other hand, if it turned out to be true, it would be a fact of vast importance to the country, from the immense saving of breadcorn which would accrue from the adoption of the system. Accordingly a small plot of garden-ground was sown, one half with good Wheat and the other half with tailing or refuse Wheat. Upon my return home after an absence of some weeks in the spring, I was surprised to see the latter covering the ground as thick as Grass in a meadow, but I found upon inquiry that the person who had the charge of the experiment considering the seed good for nothing, and quite despairing of its growth, had sown five or six times as much of it as of the other. As this quite thwarted my design of comparing the produce of both, I directed that half the thick-sown Corn should be hoed out, till the plants were reduced, as nearly as possible, to the same number as occupied a corresponding portion of the good-seed ground. The other half was left to take its chance, except that one row which happened to be above a drain, and consequently in very shallow soil, had the benefit of a watering with sulphate of ammonia. At harvest the first 12 plants in one row of each sort were taken as a sample, and the produce weighed—

	Grains.	Average of Ears per Plant.
I.—12 Plants of good Corn gave in weight	926	6·6
II.—12 do. of tailing Wheat left thick	351	3·8
III.—12 do. over drain, watered with S. A.	438	4·7
IV.—12 do. thinned out to the same number as No. I.	1187	7·2

Upon these experiments I would first remark, that sulphate of ammonia maintains its character of utility by supplying more than sounds for the infelicity of the soil; in the next place, they demonstrate very strikingly the impolicy of sowing Corn too thick where ears are wanted and not herbage. The plants, where too thick, check each other, and are too feeble to form their seed, as every Horticulturist knows. But are we to conclude from the fourth experiment that tailing Wheat is better for seed than that which is plump and heavy? Certainly not. Its superiority can only be attributed to the loosening of the soil by the hoe, and opening it to the fertilising influence of the atmosphere. This strongly recommends, however, the use of the hoe on Wheat in spring; and surely it is a great point gained in agriculture, if it can be proved that the worst seed may be made more productive than the best, if it only has the advantage of superior cultivation.

Before I conclude, I wish to mention the comparative productiveness of four different sorts of Wheat, ascertained on the same scale and in the same way:—

	Grains.	Average of Stalks per Plant.
I.—12 Plants of White Straw Wheat, gave	916	12·4
II.—12 do. of Old fashioned White do.	1432	13
III.—12 do. of Australian Prize do.	1324	18
IV.—12 do. of do., second quality do.	2424	27·2

All these were sown in the autumn, and grew nearly a foot higher than the others which were sown in the spring. Of the first two, which are the common Wheats of the country, and are distinguished by the names they usually bear, it may be observed that the number of their ears is double that of the spring crops; but the weight of the grain they produced is very little more, indeed hardly so much as that from the hoed Wheat; but this is partly to be accounted for by their greater forwardness in ripening, which exposed them more to the depredations of the birds, in spite of all the care that could be taken to protect them; and also partly by their having more small ears of a second growth, which had neither strength nor time to mature their seed. Perhaps in the spring Corn this disposition to late tillering was checked by the use of the hoe. The South Australian Wheat (No. IV.) laboured under greater disadvantages than its English brethren; for it formed its ears seven inches long, a fortnight before any other, and promised to be a finer specimen than any this country can show; but unfortunately it was attacked by the red-gum—a disease well named from the clammy exudation which discolours the ear. The insect which causes it was probably in this instance imported from Australia, for no other Corn was affected by it. If any means can be devised, as I hope they may, to get rid of this pest, the country will be under great obligations to its colony for impressing such a character of fertility upon our Wheat; and if it be true that within certain limits a change of soil and climate is beneficial to the growth of plants, no change can be more complete than by fetching our seed from the antipodes.—*E. Vernon Harcourt.*

ON MINERAL & INORGANIC MANURES.—No. III.

By PROFESSOR CHARLES SPRENGEL.

(Translated from the German.)

Having said thus much of mineral manures in their general bearing, I shall now discuss them separately, and at the same time enumerate their chemical ingredients. It is only by so doing that the way in which they act can be properly described.

1. *Lime.*—Lime, which has now been long used in Agriculture, ranks amongst the most useful of mineral manures although sore mistakes are at times committed in its application. Lime suitable for manure occurs in nature in various states of purity, and also different as to its external qualities; those most used are the varieties which Mineralogists call common compact limestone, shell limestone, rotstone or oolite, stinkstone, and chalk. On the seacoast, burnt shells are very much used as manure, which also consist chiefly of calcareous earth.

In its pure state, lime consists of 56.4 calcareous earth and 43.6 carbonic acid; but in this proportion it is only found in calc-spar (crystallised carbonate of lime) and in some sorts of marble (crystalline granular limestone). Those sorts of lime used for manure contain, besides carbonate of lime, more or less of silica, alumina, oxide of iron and manganese, common salt, magnesia, phosphate of lime, and some other admixtures, which amount at times to 8 or 10 per cent. of the whole. These extraneous admixtures partially explain the very different effects which lime manure will produce. That lime, for instance, which contains much phosphate of lime, will always act more powerfully than that which contains none, for phosphoric acid is an essential ingredient in the food of plants.

Lime is generally burnt before it is used, and thus the whole of the carbonic acid is expelled as gas. When exposed to the air after this, or sprinkled over with water, it becomes converted into an extremely fine powder (it becomes slaked), by which it is made capable of mixing more intimately with the furrow-slice. Quicklime will fix 24¼ per cent. water chemically, but will lose it again in the same proportion, as it attracts carbonic acid from the air. By losing its carbonic acid after burning, it becomes caustic, *i. e.*, it will now affect organic matter with which it may come in contact, decomposing it, and combining chemically with the substances thus generated. By the action of quicklime, organic matter is converted chiefly into humic acid. To this lime bears a strong affinity, and if previously combined with water it will lose it again through the above combination; the new compound, however, will again combine with water.

In its caustic state, lime is soluble in water, but 752 lbs. of water at a temperature of 162 deg. Fahr. are required to dissolve 1 lb. of calcareous earth. The lime-water thus formed possesses alkaline properties, and so also does the earth itself. It is easily soluble in water, if free from carbonic acid, and in this action on the organic matter of the soil it excels. In water, that substance may act upon each other, and lime must be in a liquid state; and this explains why gypsum, when dissolved in water, will have equal effects.

As long as burnt lime remains caustic, it acts on the

soil in the following manner: it decomposes the vegetable matter and the coal of humus, which, there can be little doubt, is contained in all soils; by this operation humic acid is formed, and the mineral substances contained in the vegetable matter, such as potash, soda, alumina, nitrogen, magnesia, lime, &c., are disengaged from their former chemical state of composition. It creates, therefore, as it were, vegetable nourishment, for neither coal of humus nor vegetable matter are soluble in water. With the humic acid thus generated, it combines into humate of lime; but as this substance is soluble in water only with great difficulty, the plants will not be able to take up more than the amount of lime they absolutely need. On account of its affinity to humic acid, lime will also unite with that contained in the soil in a free state, which will thus be rendered nearly insoluble, and this is exactly the contrary of what was formerly believed to be the case. Lime also frees the humic acid of the soil from the alumina, which may be found chemically combined with it, and thus also humate of lime is generated, which affords more nourishment to plants, as humate of alumina is quite insoluble in water. For this purpose, however, a greater quantity of caustic lime will be always required, and thus clayey soils must receive a greater quantity of lime than other sorts of soil, as they generally contain much humate of alumina. Lime, also, most probably decomposes the silicates of potash and soda contained in the soil, combining chemically with the silica and driving off the potash and soda, which then unite again with humic or some other acid. It further enters into combination with the hydrated silica contained in the soil, forming a silicate of lime insoluble in water; and this is beneficial, as crops (especially the Cerealia) might easily obtain through the hydrate too much silica, which would make them difficult of digestion. By this process, however, the plants are at any rate deprived of some part of the silica, which they would otherwise take up. If the soil contains much hydrated silica, the plants will not receive a sufficient quantity of lime, for it will all be employed in decomposing this compound and forming another which, as already said, is insoluble in water; manuring with lime thus often needs to be repeated several times. It is a very important fact, moreover, that lime disposes the protoxide of iron and manganese to attract oxygen from the air, and thus to be converted into oxides, in which latter state they will be useful to the crops, whilst in the former they are often detrimental. We shall find, therefore, that manuring with lime will be especially useful to ferruginous soils.

Hard clayey soils will be much loosened by a strong manuring with lime; in fact they will attain quite another texture, and this is caused by the different extent to which the two earths are distended by the absorption of water. This will be shown more clearly when treating of marl. Most probably lime also disposes the oxygen and nitrogen of the air to form nitric acid, by which nitrate of lime is formed, which is a very powerful manure. In fine, during all the decompositions and combinations which lime undergoes, electricity is developed; and this also will certainly increase the activity of the soil. Caustic lime will also act beneficially in destroying many seeds of weeds, or rather it will cause that if they should germinate they will not come to perfection. It also kills many of the lower orders of insects and worms.

(To be continued.)

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. II.

(Continued from page 27.)

Now the fertility of all soils depends upon the due proportion which they contain of the above principles. It is the object of Agricultural Chemistry to point out where any of them is deficient, and it is the object of the scientific farmer to remedy this deficiency, and to maintain the correct proportion of each by suitable and judicious applications in the form of manures.

To understand this, it is quite clear he must have some knowledge of the chemical constitution of manure as well as of plants. These subjects we shall consider hereafter.

It is also necessary that the farmer should have a standard by which the fertility of a soil, in its natural state, may be considered as a maximum in the due proportions of the above elements; and, secondly, that he should be able, by a simple process, to ascertain these proportions for himself.

Now, with regard to a standard of fertility, I confess we shall have some preliminary difficulty, because it can only be decided by experiments, and of these we have not at present sufficient to form positive conclusions. But if the point be once conceded as important, it will be soon established; for if truth is the object of experiment, I cannot for a moment doubt we shall have many volunteers in the service. All, however, that I consider necessary at present can easily be accomplished.

I propose that a "standard of fertility," which will also be a "standard of quality" of soils, should for the present be founded upon the proportions of "fine sand" and "impalpable matter."

It is the impalpable matter that gives the quality of heaviness or lightness to soils; and it will be easily observed, by looking at the general analysis detailed above, that it contains the principal inorganic and fertilising ingredients in all soils.

While, then, we only [illegible] founded upon this well-known [illegible] soils, we must hope, as Agricultural Chemistry progresses, that experiments are multiplied, for more exact data, and found a perfect standard upon a [illegible] analyses.

In all soils there is a variable amount of moisture, which can only be driven off by heat. This quantity of retaining moisture is greatest in heavy soils, or those in which there is the largest portion of impalpable matter; and the least in light soils, where that proportion is less. Here, then, we have our starting-point dependant upon our standard of fertility; for it is not necessary for me to allude to the important bearing of this quality of soils to its fertility.

In heavy soils, the amount of insensible moisture may be fixed as a maximum at one-eighth of the entire soil; the loose gravel and undecomposed vegetable fibre at one-eighth more.

Thus, if we take 400 grains, we shall have as a maximum in heavy soils 50 grains of moisture, and 50 grains of loose gravel and undecomposed vegetable fibre. It will seldom exceed this proportion, but will frequently be below it. We shall now have 300 grains, which are divisible by a very simple process into two portions, a fine sand and an impalpable powder. The question is now to decide what are the proportions of these two substances—for this will fix the character of the soil. In a heavy tenacious soil which I recently examined, the result was 108 grains of impalpable powder, 187 of fine sand, 54 grains of coarse gravel, 35 grains of moisture, and the rest vegetable and animal matter and loss. This soil the farmer told me would grow good crops of Corn, if he could but "work it;" but the difficulty in doing this was such, that he considered it the worst field on his farm. Now it would not be sound to attempt to establish principles upon a single experiment, but as the result agrees very much with the observations of others, and has been, with little variation, confirmed by other experiments, I am induced to propose one part of impalpable matter in four of the entire soil, to be characteristic of a fair specimen of heavy soil; every five grains above this standard bringing it nearer to absolute clay, and every five grains below approximating it to the standard I propose to fix for,

Light Soils.—In an excellent light soil which I examined, and which will be further alluded to hereafter, I found the following proportions in 400 grains:—

Moisture	21 grains.
Loose gravel	27 "
Fine sand	249 "
Impalpable matter	78 "
Loss	25 "
	400 grains.

* Sir H. Davy, in an excellent Wheat-soil, found three parts in five, fine sand. He does not state the proportion of impalpable matter, but assuming that one part was of moisture and coarse gravel, his analysis would be—

Moisture and coarse sand. Undecomposed fibre and loss	80
Fine sand	240
Impalpable matter	80
	400

Many good fertile light soils, particularly Turnip-lands, have a much less proportion of impalpable matter than stated here; but I think we may fairly take the proportions of 66 impalpable matter to 234 of fine sand, as a standard of a good light soil, being as one in six to the whole soil.

When the proportion is as low as one part of impalpable matter in ten of the entire soil, I should denominate such a soil sandy, the fertility gradually decreasing as the proportion of impalpable matter diminishes, until absolute sterility is arrived at, which, upon the authority of Sir H. Davy, we may fix at 20 in 400 grains, or one in 20 of the entire soil.

My standards would then come in the following order—

Barren; clay	Impalp. matter.	Fine sand.	Coarse gravel and moisture.
Fertile; heavy soils	100 or $\frac{1}{4}$ of the soil	200	100
Fertile; light soils	66 or $\frac{1}{6}$ of the soil	234	100
Fertile; sandy	40 or $\frac{1}{10}$ of the soil	260	100
Barren; sand	20 or $\frac{1}{20}$ of the soil	280	100

Between these standards there will of course be a great many shades of difference, but the character of the soil is easily determined by its approximation to the above figures. Thus, if the amount of impalpable matter in 400 grs. be from 116 to 84 grs., the soils are varieties of heavy soils; if it vary from 82 to 54 grs., they are varieties of light soils; and if it be 50, or 30, or 25, they would be specimens of sandy soils.—*C. R. Bree, Stowmarket.*

(To be continued.)

ON THE APPLICATION OF COPROLITES AS A MANURE.

Mr. Potter has directed attention (*Agricultural Gazette*, p. 10) to some observations I lately laid before the Geological Society on certain nodules, found in the crag formation at Felixton, in Suffolk, and which I have considered to be of coprolitic origin. I believe that this was not before inspected; at least I know that some of our eminent geologists were of opinion that these nodules might be only hardened masses of London clay, which had been rolled into various shapes at the time the crag was deposited, and which had subsequently undergone some alteration in their mineral character. The nature of the evidence upon which I satisfied myself that they were coprolitic need not here be alluded to; but I wish to offer a few remarks upon the probability of their being found useful for agricultural purposes. Liebig has probably allowed his enthusiasm to get the better of his judgment, when, after noticing certain strata containing Coprolites and osseous remains, he concludes his recently-published letters in this words:—"What a curious and interesting subject for contemplation!—In the remains of an extinct *animal* world, England is to find the means of increasing her wealth in agricultural produce as she has already found the great support of her manufacturing industry in fossil fuel—the preserved matter of primeval forests—the remains of a *vegetable* world. May this expectation be realised! and may her excellent population be thus redeemed from poverty and misery!"

Devoutly as we may all desire such a consummation, let us neither too hastily adopt nor yet too hastily reject these speculations of the German chemist. If he is correct in supposing that the phosphate of lime contained in fossil bones and Coprolites can be economically converted to the same purposes as that in recent bones, his observations will be worthy the most serious attention of Agriculturists; but even if his kindest wishes for our national prosperity are not likely to be realised, coprolitic deposits may still turn out to be of great local importance. Mr. Potter's interesting analysis gives as much as 58 per cent. of phosphate of lime in the coprolitic nodules of the crag! It will be a subject for statistical inquiry whether they can be collected and pounded, or otherwise prepared, with sufficient economy to make them serviceable to the Agriculturist. The collecting iron pyrites by hand along our eastern coast is found to pay well; and certainly it appears to me not improbable that it would require much less labour to collect a ton of Coprolites at Felixton than of iron pyrites. I do not understand why Mr. Potter has supposed there is any difficulty in distinguishing them from pebbles by their external appearance alone; a very slightly-practised eye could never make the mistake. The children employed at the Cornish mines to separate the broken fragments of ores into three or four samples have a much more difficult task, which they accomplish with unerring certainty and wonderful rapidity, and a single day's lesson would be sufficient to teach any one to distinguish these nodules from rolled stones. I do not recollect that they are found in any quantity upon the beach; and the impression on my mind is, that they soon disintegrate or decompose when exposed there. The rounded form which many of them present is not due to attrition, as Mr. Potter suggests, but is the shape they have assumed naturally. Very many of them contain evident traces of the dermic apparatus of crustaceans, and in some instances the entire forms of crabs are distinguishable. This may possibly account for the very high proportion of phosphate of lime which Mr. Potter has detected in them, and it may be important to ascertain whether this character uniformly prevails. In considering these bodies as coprolitic, I do not suppose them all to have been the digested materials devoured by sharks, though some of the specimens affect the character of Coprolites from other formations, which have been so esteemed; but the more common character of these Coprolites is to have the material folded longitudinally, in a thickened convolution round an axis which is frequently perforated. The fold in the intestines of sharks and rays is transverse. It may be worthy of inquiry whether some of these nodules may not have resulted from the presence of animal matter which has never been subjected to the digestive process; and, in connection with such inquiry, is the remarkable fact, that numerous traces of Cetaceans are found intermixed with these nodules. Fragments of their bones occur in considerable abundance, and whilst pursuing the investigation, I picked up what appeared to me a much-rolled portion of the tympanic bone of a whale's ear. This awakened attention, and further investigation furnished me with several specimens. I thought I saw sufficient evidence for believing that these ear-bones must have belonged to four, if not five, species of whale, and I sent them to Professor Owen for his better judgment on such points. He has decided that this is the case, and has drawn up specific characters for four species, referring them to individuals of the genus *Balæna*. The specimen which Mr. Deck has since found I have seen, but I believe it belongs to one of the four species named by Professor Owen. It is certainly a very remarkable circumstance that these Fossil remains should be so very abundant just at one spot in the cliffs, and there associated with so large a number of coprolitic nodules. I notice these circumstances a little in detail, in hopes of awakening further attention to the subject. Very possibly there may be other localities in the crag, where Coprolites are equally abundant; and it may afford others, when spending a few weeks on the east coast, as much amusement as I have myself received in working out their history. It is one of the incalculable advantages which a slight knowledge of natural history is always found to confer, that we cannot visit a spot upon the earth's surface without meeting with a sufficiency of occupation for our thoughts in such investigations as these. I heard Felixton so thoroughly condemned as a watering-place, that some persons would not stay there more than a night or two, and yet it is seated in one of the noblest bays in England, with excellent and safe bathing, possessing a maritime Flora of much interest, with a fine denudation of one of the most remarkable of our British strata, and has, moreover, the alluvial soil filled with fragments of Roman pottery mixed with the well-preserved remains of deer, oxen, and every other description of animal, including snails (!) which the Romans had fed on 1400 years ago, intermixed with coins and other objects of antiquarian curiosity. But if these Coprolites are worth thinking about, I do hope that no time will be lost in testing the question of their value as an agricultural manure. It only requires a small outlay of some 20*l.* or so, to have a number of them collected, properly prepared, distributed in small packets to willingly-disposed experimenters, with a schedule of directions for securing comparative results, and then before another year has passed away we may be in a position to say ay or no to Liebig, and bid him try again. May we hope that some one of our Agricultural Societies may consider the question which is to be solved quite as well worthy as

effect as those others upon which public funds are expended. —*F. B. Hensloe.*

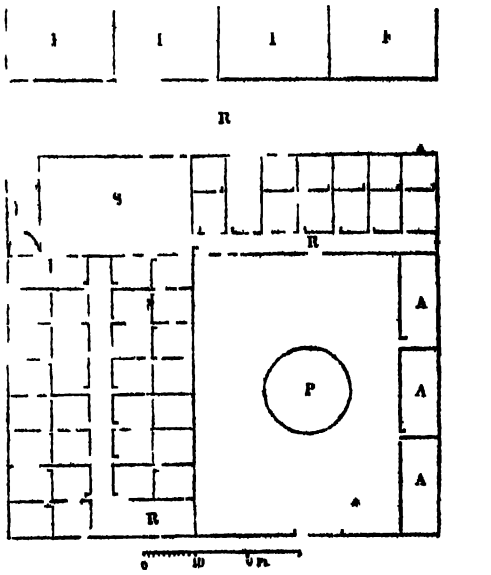
Home Correspondence.

Slugs on Wheat.—The method recommended by "S N. V." in the Number of this *Gazette* for January 6, for preventing the ravages of these molinscs, I found in practice in 1814, among the farmers of West Middlesex, who had adopted it from the market gardens nearer the metropolis; but about that time a modification of the process, at once cheaper and more effectual, was discovered, which superseded the old method The improvement consisted in giving these gentry a belly-full of food, relished by them more than the Wheat This was no other than the Turnip-tops, to which, when first used, our slimy friends were supposed to be attracted by the shelter which they afforded in the night, whereas, in reality, they repaired to them for the gratification of their palates The discovery was made by accident—I think upon the farm of Mr. Newman, of Cranford—during a long course of wet weather, which prevented the gathering of the slugs for some days, at the end of which time it was found that they had devoured the traps set for them, and had spared the Wheat. Not liking the expense of collecting the slugs by women and boys, I had tried sprinkling the field with lime or salt, in the night, while the slugs were feeding, but, though thousands were killed, it seemed as if tens of thousands came to the funeral. From the time, however, that I commenced the feeding system I never lost an acre of Wheat from the slug, though the district, in a mild wet autumn, was very liable to their ravages, on Wheat after Clover. In a very bad slug season, I once covered a 15 acre-field so thickly with Turnip leaves that the surface was scarcely visible, and in less than a fortnight all the leaves had disappeared except the stalks, which remained like the tails of the Kilkenny cats, and on which the slugs were hard at work, without having touched the Wheat, when I served them up a second course This, however, will seldom be necessary, if the leaves are applied liberally and early after sowing for in a fortnight or three weeks the plant will in general be too strong to suffer by the bite of the slugs. The feast must, however, be given early, for they commence the attack on the Wheat almost before the plant has shown itself above the surface The process was discovered, as I have said, by accident, but it shows strongly the advantage to the farmer or gardener of studying the habits of all animals that are noxious to him, and of supplying them with food more congenial to their tastes than that which he wishes to preserve from them. This method, or that of setting a thief to catch a thief, by concluding an alliance offensive and defensive with some other tribe of animals, who wage war with our enemies, will often be found cheaper and more efficacious than taking the work of destruction into our own hands. I think it is Kirby and Spence who have said that the more wasps we have in our gardens the fewer flies shall we have in our parlours—the more lady-birds in our greenhouses the fewer aphides on our Rose-trees; and the Hop growers in Kent well know the money-value of a swarm of lady-birds Though not prepared to point out the office performed by slugs in the economy of nature, I have no doubt that an office is assigned to them; for each creature constitutes a link in the great chain of being, dependent upon others which suffer by the diminished numbers of those creatures on which they prey, and which, in their turn, have enemies appointed to keep them within due bounds. The proscription of rooks and sparrows by the collective wisdom of some parishes, in vestry assembled, has been known to have occasioned more loss to the farmer by the ravages of insects than would have paid many times over for the cost of watching his crops against those birds in seedtime and harvest Of rooks I must observe, by the-way, that a solution of corrosive sublimate—used as a steep for seed-Wheat, under proper precautions, and in proper proportions—is not only the best preventive against smut I ever met with (and I have tried several), but will also preserve the Wheat from rooks, who just taste it, shake their heads at it, and go off to some other field till the grain has sprouted, when the services of the bird boy must be put in requisition Unless, however, care be used, there is danger not only of killing the Wheat, but of poisoning all the pigs and poultry in the farm-yard,—their pampered habits having rendered their wits more obtuse than those of the rooks, whose intellects, naturally acute, appear to have been sharpened by poverty and persecution. With care, however, no danger is to be apprehended, I have used the steep for nearly 10 years with complete success; the only loss occasioned by it being about a dozen turnips and two quarters of seed-Wheat, which occurred in the first year. The necessary precautions, and the details of the process, I shall describe on a future occasion —*J. Trimmer.*

Oats.—In 1st Number of your *Gazette* an experiment with manures is detailed in which the one I am chiefly interested in does not appear to have answered so well as others, publication of which is calculated to injure me I inclose you a letter I received from Mr Reeves, Lord Ashburton's agent, in which he has found quite the contrary effect.—*Ed Purser, London Manure Co.*—" Taunton, December 2, 1843 —A farm of Lord Ashburton's having fallen into hand, in the parish of Cotleigh, near Honiton, in Devonshire, in very bad condition, I took possession of it in the month of October, 1842, and, with permission of his Lordship, began to farm it. I commenced with an arable field of six acres, which was very wet, and intended to have been sown with Wheat. I thoroughly drained it with stone, at the depth of three feet, but it was too wet to subsoil. I then divided it into separate portions, and amongst many other artificial manures, I applied the London Manure Company's urate as a top dressing immediately after the Wheat (the Taunton White Wheat) was sown, and harrowed the land twice. Besides the artificial manures, I applied lime and farm yard dung to separate portions of the field. The Wheat on the portion of the land on which the urate was spread, came up with great vigour, and maintained a decided superiority to the whole field during the period of its growth, and yielded ten bushels an acre more than the other parts of the field; and what is very remarkable, there was neither smut nor rust in any part of the Wheat grown on this portion of land, although, on the other parts of the field, both smut and rust were seen The superiority of the Wheat on the portion of the field before mentioned is so notorious, that all the farmers at Cotleigh can testify to it, and marked its progress during its growth, and I shall feel great pleasure in giving further information to any person wishing more particulars on this subject Yours, very faithfully, *J F Reeves*' [We are happy to receive *authenticated* reports of the action of the various manures from any person, and if of sufficient importance shall publish them, whatever their tendency may be, our object being to disseminate truth for the benefit of the farmer]

Malting —Being desirous of ascertaining the quickest mode of causing Barley to sprout sufficiently for the purposes of malting, in order, if possible, to lessen the time usually occupied in that process, I conducted a series of experiments with that view You will be aware that if any material be available for that purpose it must be something soluble in water, and which can thus be applied in the water in which the Barley is steeped in the cistern The different materials I tried as compared with common clean water, were, salt and water, lime water, ley from wood-ashes and one or two more, which, though I registered the experiments very minutely at the time, I do not now remember, for seeing no decided result, I did not retain the papers The objects sought to be achieved, are rapidity of germination, in its first process only, and as large a bulk of material as can be had besides, for if there was a diminution of the article it would cause a loss These two main points must, if accomplished be done by something which will be wholesome in itself, and which will impart no disagreeable flavour to the Barley.—*Cardinal Wolsey* [We should try the effect of moistening Barley with warm water, and then dusting it with *newly slacked lime* It might be tried on a small scale, and the result of experiments on the subject would be useful]

Leases. — Much has been said and written by practical as well as theoretical Agriculturists upon the momentous subject of leases and draining, but, up to the present moment, there does not appear to have been one decisive measure proposed to enable these important objects to be practically applied; and, perhaps, while attempting to recommend, I, as others have done, may fail to succeed however, by the joint efforts of many, difficult objects may be surmounted, and in that hope I will proceed. First,—I would recommend leases to be granted for 21 years, under conditions suited to the nature and situation of the farm, terminable, if required by the occupier, at the expiration of 6 or 12 years the rent being regulated triennially, or otherwise, as may be judged expedient, according to the average price of Corn during the 6 preceding years in the district wherein the parliamentary return is made—observing, that the basis of rent at the commencement of each lease should also be fixed upon the same principle of Corn averages It would be well if farmers in general could be brought to the same arrangement, notwithstanding existing leases. Secondly,—With respect to draining, I would recommend that 10 per cent of the rent should be laid out annually in draining (if the land requires it, and there are few instances where it does not) during the first 6 years, and that at the end of that term the tenant should pay 4 per cent for the outlay as additional rent, by which time the land would in a great measure be made dry, and the occupier, during the remaining period of his lease, would be enabled to realise an increased produce, owing to the transformation of his land from wet to dry, and thus have a more genial atmosphere and earlier harvest insured to him —*An Agriculturist.*



The Berberry Blight —It may not be uninteresting to such of your readers as have paid any attention to the subject of the supposed influence of the Berberry on the production of mildew in Wheat, to learn that some observations on this matter, by very competent persons, are likely to be published by the Royal Society of Lille, of which I have the honour of being a member. A commission was appointed by the Society last summer, consisting of practical men, in conjunction with that excellent cryptogamist, M. Desmazieres, a gentleman who has paid peculiar attention to the parasitic fungi, for the purpose of thoroughly investigating the point; and I understand from M Desmazieres, who joined the commission with an impression that the supposed influence was altogether fabulous, that the result of their inquiries was a complete conviction that a very marked connection did exist between the presence of the Berberry and mildew When the observations are published, I shall have great pleasure in laying a translation of them before your readers I do not offer any opinion on the matter myself, but shall content myself with remarking that, though there is not the slightest reason for supposing that the parasite on Corn is an altered form of that on Berberry, however extraordinary are the changes which take place amongst these minute plants, as, for instance, that of the Uredo-like spots on the leaves of Roses, and Burnat to Aregelia and Nemodechium, there may be some influence exercised either by the exhalations from the leaves and flowers, or by the substance given out by the roots, which may predispose the Wheat plants in their neighbourhood to the attacks of mildew. At any rate, in this, as in other matters, the way to arrive at truth is to keep the mind, if possible, quite free from prejudice, and ready to weigh impartially whatever trustworthy observations may be brought forward.—*M J. Berkeley, King's Cliff.*

The Loss of Manure in Towns —Every shower of rain washes much valuable manure down our public sewers and drains, and thence into the rivers and the sea; and thus while we employ ships in fetching guano many thousands of miles to enrich this country, we will not pick up that which lies under our feet The streets are swept indeed, but little more than the gravel, sand, and litter is saved; the finest and the richest parts are taken away by the rain. There would be no difficulty in forming reservoirs into which all this might flow, and from which it might be transferred to enrich the grounds But it is of the greatest importance in another point of view that towns should be well drained and cleansed, and as a proof of this I make the following extract from a lecture delivered a few days ago on the sanitary condition of this town, by the Rev. J Clay, M.D. He stated the number of deaths in the streets of the town, arranged according to the condition of their drainage, as follows:—

Ages	Good		Moderate		Bad	
	Deaths	p. ct.	Deaths	p. ct	Deaths	p ct.
Under 1 year	2	15 3	188	20 8	250	32 9
Between 1 & 5	26	19 3	286	31 8	310	39.2
Above 5	88	65 2	364	47 9	193	29.5
	135		760		803	

In the best streets the deaths above five were about double those under five, in the moderately-drained streets about equal but in the ill-conditioned parts of the town the deaths under five were two-and-a-half times as numerous as those above. These facts were striking and appalling —*Lancet, Preston*

Plan of Piggery —This piggery is constructed for the purpose of breeding and feeding on a scale to suit a farm of 600 acres of Turnip soil in an inland situation, where convenient markets render the disposal easy both of fat and lean stock The seven sties on the end of the steaming house accommodate a boar and six brood sows, which

are calculated to produce yearly 100 pigs, 60 of which will be fattened from September till April in the 15 sties placed in two rows, which will contain two hogs in each apartment The remainder will be sold as stores. The yearly return will be from 200*l* to 250*l*., according to the price of the produce. The steamed food will consist of Potatoes, meal, and grain to finish, and it will be conveyed to the sties along the paved road in a small four-wheeled waggon. The steamer also cooks Potatoes for work horses, and chaff for milch cows; and thus applies the cost to several purposes, and fully employs a man. The store-pigs are fed in summer with Clovers and Vetches, and in winter with steamed and raw roots. Water is brought to the steaming-house in a pipe from the farm-yards, which are all supplied by ball cocks from elevated casks, fed by a forcing pump, a pipe underneath conveys the water from the Potato-masher to the pond in the store yard, whence it passes to the lower corner of the yard, where it meets with the collected water of the whole area of the piggery, falls through an iron grate into a paved culvert, and is conveyed to the manure pit, to which the liquid of the farmery is collected by a drain along the side of the road. The expense of this piggery will vary from 80*l*. to 100*l*., according as the roof be slate or tiles, and according to the local prices of labour and materials. The steaming-house is covered above for holding meal and grain for steaming, and the roots are laid on the ground-floor, and let in from the carts by a spout-hole in the wall.—*J. H.*

Cultivation of Flax.—By their neglect of the cultivation of Flax the farmers and landowners of this country have sadly overlooked their own interests. Flax is now annually imported in this country to the amount of [illegible] principally, the value of which at a low [illegible] from 4,000,000*l.* and 5,000,000*l.* [illegible] of this raw material is [illegible] Continental neighbours—the Belgian, Dutch, and Belgian,

farmers. I have had seven years' experience as a grower of Flax, and 12 years' practical knowledge as a buyer and agent for several of the largest Flax-spinners in Leeds, Manchester, and Preston; and I am prepared to place before landlords and farmers my views, which, if followed up by them, will soon stop the call for Belgian, French, Dutch, or Riga Flax; and thus we shall keep the 5,000,000*l.* sterling in the hands of our own farmers, instead of sending it abroad. All the difficulties in the way of the culture of Flax may easily be overcome, unless it be the Irish superstition, which imagines that St. Patrick blessed the Shamrock shores and the county of Down, while, although in view of the Lancashire coast, he would not notice it. I am prepared to prove that there is as good soil in Lancashire, and other parts of England, for the cultivation of the Flax-plant, as in Ireland, France, or Holland; and, as I can also prove, that farmers can, by growing Flax, clear greater profits per acre than they can by growing Wheat or Barley. There have been instances of 60*l.* per acre, clear of all expenses, made this year in the north of Ireland by parties who went to work on the Belgian system. Intelligent young farmers have of late years been sent to Belgium and France, and by them, owing to the adoption of an improved management, the quality of British Flax has been greatly improved. The quantity grown in our country has also increased so much, that, at the last meeting of the Society in Ireland for the improvement of Flax Culture, one spinner declared that previously he generally paid 40,000*l.* per annum to the Continental growers for Flax, and that the last year he has not paid 40*s.* I can prove that the small farmers, holders of from 30 to 60 acres of ground, can now make by an acre, or two acres of Flax, what will pay their rent for 30 to 60 acres. This never could be done by six acres of any other kind of grain. This almost new and improved system has so extended itself, that branches of the society for improvement have been established in every direction. In the North, 112,000 acres were sown last year, and the calculation is, that the value of the produce at the low price of 45*l.* per ton would amount to 1,767,150*l.* At the same time, I know that some has been sold so high as 140*l.* per ton, and a great deal at 64*l.* and 100*l.* per ton. I have had many years' experience and know well the processes that the Flax plant must go through before it appears in the beautiful white cambric, damask, or linen—the processes of sowing, weeding, pulling, watering, scutching, hackling, spinning, and weaving. I shall have pleasure in giving you every information in my power on this subject from time to time.—*J. H. Dickson, 8, Manchester Buildings, Whitehall.* [We are sorry that we could not insert the whole of Mr. Dickson's letter. We shall be happy to receive the communications on this subject which he promises.]

Wireworm.—I know not whether it may be generally known that pheasants are destroyers of that mischievous grub, the wire-worm; it may possibly, therefore, be acceptable to some of your agricultural readers to be informed that such is really the fact. A correspondent of the "Sporting Magazine" writes, "that no fewer than 1225 of those destructive larvæ were taken from the crop of a hen pheasant in January last." Consider, that this is only one day's consumption! It thus appears that pheasants are of some benefit to the farmer.—*A Quiet Observer.*

Societies.

HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND.

The anniversary general meeting of this Society was held on Jan. 9th, in their Hall, Albyn-place. There was a large attendance of the members. The Right Hon. the Earl of Mansfield, one of the Vice-Presidents in office, took the chair. The first business before the meeting was the balloting for new members, when 38 candidates were unanimously elected. The Duke of Richmond was then re-elected President of the Society for the ensuing year, being his fourth year in office; and the Marquis of Queensberry and the Earl Cathcart were elected Vice-Presidents in room of the Earl of Seafield and Lord Dunfermline, who retire by rotation. Among other matters then submitted to the meeting, the Secretary stated the results of the competition for the premiums in the year just expired. There had been 14 papers sent in, reporting experiments with various special manures, and no class of premiums, in the remembrance of the oldest Director, had given rise to a more satisfactory competition. The first premium of 50*l.* was awarded to Mr. John Hannam, Wetherby, Yorkshire; the second premium of 30*l.* to Mr. Alexander F. Gardiner, overseer to Mr. Fleming of Barrochan; the third premium of 20*l.* was equally divided between Mr. Finnie, Swanston, and Mr. Stevenson, Redside, near North Berwick, these two papers being considered of equal merit. But not satisfied with these awards, the Directors considered the other ten papers of so much value as to induce them to recommend that they also should be printed for the benefit of the public. They therefore proposed that an extra sum of 30*l.* should be appropriated in awards for these papers. The circulation of the "Quarterly Journal of Agriculture," in which the Prize Essays of the Society are published, was stated to amount to 2200. The thanks of the Society having been voted to its office-bearers on the occasion of the late Show at Dundee, arrangements were made for the nomination of a Committee to superintend all the arrangements for the Agricultural Meeting and Show of Live Stock to be held at Glasgow on the 7th, 8th, and 9th August next. The report of the Committee on Cottage Premiums was then read, and it was agreed that [illegible] competed for the premiums [illegible] to the end of March. All cottages [illegible] and on or before 15th [illegible], Chairman of the Committee on the [illegible] report on the state of that establishment, [illegible] continue to be afforded to the public of free admission, [illegible] the numerous and valuable objects which the collection exhibits in its various departments; and a reference to the visitors' book gives satisfactory proof that the privilege of admission is duly appreciated. It has been opened only two years and a-half, and within that time 17,585 have inscribed their names as visitors. Donations of models of implements, seeds, roots, plants, timber, and geological specimens continue to be received and added to the collection. Not the least interesting of these are the samples of agricultural produce from the various Local Associations, thus enabling them to form a comparative estimate of the value of the crops throughout the country. Towards the close of the meeting, Sir John Graham Dalyell stated that he had often wished that some gentleman would devote his attention to the drawing up of a short history of this Society, which had rendered such immense benefit to the country. The first Agricultural Society that ever existed in Scotland he found was instituted in 1723; the next was in 1755; and the present patriotic and powerful Society was begun just 60 years ago. He thought all that was to be desired might be condensed into a brief memoir, which the members might find both agreeable and useful. He had collected various notes on the subject himself, which he would be happy to hand over to any gentleman who would undertake this task. The business being concluded, thanks were voted to the noble Earl in the chair, after which the meeting separated.

AGRICULTURAL SOCIETY OF IRELAND.

The council of this Society held their weekly meeting on Thursday, January 11. A report on the profitable reclamation of waste lands in the King's County was received from W. S. Trench, Esq., of Monaghan. Reports, competing for the Society's gold medal, for the greatest quantity of draining executed in Ireland for the years 1842 and 1843, were also received from several gentlemen. Committees were appointed for their examination. A sub-committee was also appointed to select and report upon the best and most eligible situation for holding the next great cattle show in or near Dublin, on the 14th of August next; and the council then adjourned until Thursday, the 18th instant, at two o'clock.

AGRICULTURAL CHEMISTRY ASSOCIATION.

The Annual General Meeting of the members of this Association was held on Jan. 8th, in the Highland Society's Museum, Lord Melville in the chair. From the Report by the Committee of Management, it appears that the society is rapidly increasing in number; nearly a sufficient sum has been subscribed as the salary for 5 years, of their chemist, Prof. Johnston. The Professor is now resident in Edinburgh, and is amply provided with all the requisite apparatus, and with three able assistants, whom he has engaged at a considerable cost. Two of these are foreigners, and all of them experienced chemists. They have already begun work, and indeed for the last few weeks have been actively engaged not only in answering letters of advice, but in analysing soils sent them from different parts of Scotland, and also from Jamaica and Demerara, by subscribers there, and in examining likewise various marls, and specimens of guano, oil-cake, turnips, &c., which have been forwarded from all quarters of Great Britain and from Ireland. Two important additions have been made to the regulations of the society. By the one, counties subscribing 20*l.* yearly to the Association have the privilege given them of sending a member of Committee of the Board of Management. The other regards a point which was stated at last general meeting to be under consideration, viz., the terms on which local Agricultural Societies should have lectures from Professor Johnston. These have now been fixed at 5*l.* for each lecture, which are not to exceed three in number, besides the travelling expenses of Professor Johnston, and this regulation appears to be giving satisfaction. Already application has been made by various agricultural societies in the counties of Renfrew, Ayr, and Fife, for lectures, and it is understood that the example will soon be followed by others. The state of the funds has improved greatly since last general meeting. Some very handsome contributions have been received. That of the Duke of Northumberland, of 30*l.*, merits especial notice, as an instance of disinterested liberality—since his Grace possesses, it is believed, no property in Scotland. Nor must the conduct of the West Lothian Agricultural Society, in contributing 10*l.*, pass without remark, as it evinces an enlightened zeal in the ranks of our practical agriculturists.

FARMERS' CLUBS.

Maidstone.—The annual report which was read at a late meeting of this club records the resolutions of the club on the various subjects discussed during the past year. Among them the following seem of general importance:—At the March meeting on the subject of feeding off Wheat, it was resolved, "That it is the opinion of the members that no good is derived from feeding off Wheat, but that the treading of Wheat, or rolling it with the clod-crusher on light soils, is considered extremely beneficial, and that good crops have resulted from these operations, by which the wire-worm has been checked, and the soil effectually closed." On October 5th the subject of discussion was the cultivation of Wheat, which resulted in the following resolution:—"That on land where it is practicable, crossing or drilling is always preferable, as two bushels of seed thus used will be found equal to at least two and a half bushels sown broad-cast. Dibbling, when labourers can be got to do it properly, will cause a still greater saving of seed, and give greater employment. That in this district the quantity of seed usually considered necessary is from two bushels to two and a half bushels, according to the interest of the season; but that the system of thin sowing, as recommended in Mr. Davis's recent pamphlet, appears highly deserving of consideration and experimental trial."

Rhins of Galloway.—The first monthly meeting of this Club was held at Stranraer on Friday, 29th Dec. Mr. M'Bryde, the Secretary, delivered an interesting address descriptive of ancient Agriculture, and afterwards opened a discussion on the growth and cultivation of Wheat. A variety of communications upon this subject received by him from farmers in various parts of the kingdom were read to the meeting, from most of which it appeared that Hunter's Wheat was a hardy and profitable variety, and that it was advisable to change the seed every two or three years, taking care always to obtain it from a better and earlier soil and climate.

GEOLOGICAL SOCIETY.

Native Phosphate of Lime.—At the last meeting of this Society, Professor Daubeney read a paper on the occurrence of Native Phosphate of Lime in the province of Estremadura, in Spain. This salt occurs near Guadaloupe, and forms a vein running between the chip slate for about two miles, and is about 20 feet in breadth, and, as far as could be ascertained, 10 feet in thickness. Dr. Daubeney examined this formation with an especial view to ascertain the possibility of its being used in this country as an article of manure. There are, however, great difficulties existing with regard to carriage, which, on account of the unsettled state of the Peninsula, would be serious. If, however, there should at any time be a scarcity of bone manure, it might be brought to this country as a substitute. No experiments have at present been tried with this mineral as a manure, but there can be little doubt that it would act efficiently, where plants require Phosphate of Lime.

Reviews.

Productive Farming; or, A Digest of the Recent Discoveries of Liebig, &c. By Joseph A. Smith, Lecturer on Agricultural Chemistry. Second Edition. Simpkin, Marshall, and Co. 8vo., pp. 179.

It is not to be expected that farmers, as a body, should be capable of applying scientific laws to the improvement of Agriculture. In the process, however, of thus applying those laws they have a very important part to perform. They have not only for the most part to supply the materials, a consideration of which enables the scientific man to suggest improvements in their practice, but they have also to carry out these suggestions into actual trial, and to determine on the farm their real value to the farmer. Their assistance is thus required from first to last in the work of Agricultural improvement, and in order, on the one hand, that they may be able to select and state properly such facts as bear on any subject that may be under consideration; and on the other that they may be able to appreciate the suggestions founded by the scientific man upon these facts, it is of great importance that they should possess a general knowledge of the relations in which farming in its various branches stands to some of the sciences. We are therefore glad to see works of the class to which Mr. Smith's little volume belongs increasing in number.

"This book is a compilation. The object of its compiler has been the simplification of the more strictly scientific and technical writings of the principal Agricultural writers of the present age." So says its Preface. The object of its Author is a good one, and the plan laid down for its attainment has been skilfully executed.

The possibility, and indeed the certainty, that the application of scientific knowledge will eventually simplify and cheapen the farmer's practice, is well illustrated by Mr. Smith in parallel cases drawn from other arts and professions. Thus—

"Calico printers for a long time have used the solid excrements of the cow in order to brighten and fasten colours on cotton cloth. This material appeared quite necessary, and its action was ascribed to some latent principle or material derivable from the living animal. But since the action of cow-dung was known to depend on the *phosphates* contained in it, it has been completely replaced by a more cleanly mixture of certain salts, of which the most prominent is *phosphate of soda*. So, in medicine, for many centuries the mode of action or the active principle of all remedies, was veiled in obscurity. But now these principles have been presented to the world in an extremely active and concentrated form. The extraordinary efficacy of Peruvian Bark in the cure of fever is found to depend on a minute quantity of a crystalline substance, termed *quinine* contained in it. The inhabitants of Savoy are much infested with the disease known amongst us as 'Derbyshire neck.' *They* have springs which are famous for its cure; *we* derive benefit from the use of burnt sponge. Now, burnt sponge contains iodine; and upon examination these springs contain iodine in small quantities."

Apply all this to Agriculture and we may be sure that—"A time will come when fields will be manured with saline solutions, with the ashes of burnt straw, or with salts of phosphoric acid prepared in chemical manufactories, with as much certainty as now, in medicine, iodine cures the 'Derbyshire neck,' or as quinine is substituted for the bulky powdered bark in fever."

The Book of the Farm. By Henry Stephens, Editor of the "Quarterly Journal of Agriculture." Part XVII. William Blackwood and Sons.

A work [illegible] like this the above would not properly designate [illegible] Mr. Stephens goes into such detail on [illegible] subject which he discusses, that he appears

n also at making his "Book of the Farm" suitable as a substitute for a whole Agricultural library. Though eminently a practical treatise on Agriculture, this Work is frequently illustrated by scientific explanations. These are from the pen of Dr. Henry R. Madden, of Penicuik, near Edinburgh. In the present Part, the Author continues and concludes his remarks on the treatment of stock in summer, and takes up the important subject of the woods of Agriculture.

The only fault we have to find with this Work is its prolixity. Notwithstanding that it is specially addressed to Agricultural pupils, and must therefore enter fully into detail, yet it might be advantageously condensed. Mr Stephens is already greatly beyond the original limits laid down as the extent of his work, and as he has not yet got entirely through all the subjects to be treated of in it, if in that which remains he does not adopt a more condensed style, the "Book of the Farm," though certainly complete as a work of reference, will ultimately be very expensive.

Miscellaneous.

Thorough Draining.—You are quite aware that your soil is wet, and your climate is wet, and I am sure that you all must have seen that wherever there is a piece of land drier than another, you find it a fertile soil. That dryness has been affected, in some measure, by nature; but art should follow up what nature has pointed out as advantageous. If we would proceed to do so—if we would actively set to work—I am persuaded that we could soon extend fertility over the whole soil of this splendid country. If landlords and tenants, on an extended scale, would unite their energies, the landlord in assisting the tenant, and the tenant in supporting the landlord, we would soon see the country around us converted into a fertile garden. It is quite clear, from the attention which has been paid to this great meeting of the agricultural interest by extensive land-proprietors, that there is no want of an anxiety for the improvement of Irish agriculture. While this spirit of anxiety exists, the question put by the tenantry is—where are the funds to come from? We see the necessity for improvement; we would wish to have a good system of agricultural affairs; but where are the pecuniary resources? That is the great difficulty; but it is not incapable of being obviated. The improvement should be judiciously and extensively carried on by the landlords themselves. They are possessed of wealth, and they should not be afraid to lay it out on their property. It will not be thrown away. No man can finally be a loser by the improvement of his property. I can speak from experience and from extensive observation; and I know that there are hundreds of landlords in this assembly who can bear me out in the statement—that if money be laid out extensively in thorough-draining, they will not regret the expenditure. The grand secret in thorough-draining is to adopt the more substantial mode instead of the cheaper; and I would take this opportunity of warning both landlords and tenants against the danger of doing the thing superficially. When once effected, the improvement is permanent. It is a lasting good. It should be done in the most permanent manner. You should not, by any means, stint the number of drains, but you should take care to drain the land thoroughly, for I would almost as soon not see the work set on foot at all, if it were not to be fully and satisfactorily completed. There is abundance of skill and knowledge in the country; and if you would take pains to bring that skill and knowledge to bear in a proper manner, I have no doubt the work would be well and permanently accomplished. The depth of the drains is an important point. I certainly am of opinion that the drains should be at least two and a-half feet deep, and then you will have a much more perfect drain than you could possibly have by a shallow drain.—*Mr. Smith, of Deanston, at the recent Meeting of the Irish Agricultural Society.*

Lower Turnip Shear.—I beg to say, that on cutting a quantity of Aberdeen Turnips, which serve as a feed for two heifers, and which weighed without the basket 5 st 4 lbs., this implement performed the work without hurry in one minute and about ten seconds, or rather under. It would take nearly half the time to put them into the basket without cutting. A little boy who assists in my yard supplied them to the machine out of the heap, but I think the person who cuts could do all in one minute and a half at most.—*F. G.—Dublin Farmers' Gazette.*

Notices to Correspondents.

Communications from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them —*J. Snow* and *A. Campbell*.

AGRICULTURAL EDUCATION.—*R P*, *A Subscriber*.—The counties in which a person may best obtain a thorough knowledge of practical farming in every branch are situated on the eastern and northern coasts—any Norfolk, Lincolnshire, and North Scotland.

APPLICATION OF GUANO.—*A Reader*.—From Sprengel's work on Inorganic Manure, which is being published in this Paper, you will understand the action of lime on a soil. It unites with the humic acid, which is one of the forms that decomposing vegetable matter assumes in the soil, and forms with it a compound soluble in water, by which it is conveyed into the plant. When too much lime is added to the land all the available humus is immediately appropriated, and being thus conveyed into the plants, causes them to grow vigorously; but unless manure be soon applied to compensate for this loss of humus, the soil will become exhausted, which is too often the case under the rapacious cultivation of some who have only a yearly interest in the land. The carbonate of lime, as an chalk, acts in a similar way, but more slowly, and therefore more lastingly. We do not think it would be advisable or economical to burn the chalk. Perhaps its efficiency depends in a measure upon its containing phosphoric acid in small quantities, which Professor Sullivan informed us in his late lecture, is an ingredient of some varieties. If so, its value is independent of the influence which a red heat would have on its composition; and it is difficult to account in any other way than this for the benefit which, in the case of chalk, the farmer derives from repeated applications to the surface of his land, of the material dug immediately out from beneath it.

APPLICATION OF GUANO.—*Northumbriensis*.—You had better apply it before the end of April—the earlier the better. If the field is to be fed later than that, apply it as soon as the cattle are shut out.

BOOKS.—*A. N.*—You cannot get all you want in any one book, unless it be an Encyclopædia, and perhaps "Johnston's Encyclopædia of Agriculture" would suit your purpose better than any other. The best treatise on the management of poultry in all its particulars is that by Peter Boswell, Greenlaw, entitled "The Poultry Yard."

CHICKWEED.—*A Subscriber*.—We know of no other plan for destroying this weed than the diligent use of the hoe. If there be a danger with some of your crops of hoeing up the young plants with the weeds when just above ground, sow in the drills with them some Oats; these will spring up first, and show you where the others will come after, so that you may use the hoe between the rows without danger.

DRAINAGE.—*A Subscriber*.—We have seen land, such in its texture as you describe, perfectly drained with stone drains, 8o inches deep, and 16½ feet apart. Their direction was down the greatest descent.

EGYPTIAN PEAS.—*A new Subscriber*.—It is the English variety which is employed. The Messrs. Ransome, of Ipswich, manufacture an efficient corn-crusher. We shall ascertain for you further particulars regarding its use as food for cattle. Lucerne when grown on deep loamy soil may be depended on for feeding stock from May till October.

ITALIAN RYE.—*A.*—We have communicated your desire to Mr. Parkinson. We understand the M. Wurtzel, otherwise suitable as food for milch cows, is not very productive of *richness* in the milk.

LIQUID MANURE.—*A Subscriber*.—Your letter has been received, but we very rarely insert among our Home Correspondence any which merely ask questions. We either answer the questions they contain, or place them in the hands of persons competent to do so; simply publishing the answer. The quantity of sulphuric acid necessary to fix all the ammonia in a given quantity of urine will depend upon the strength of the two liquids—the latter varies considerably in the quantity of ammonia which it contains. As long as any effervescence attends the addition of the acid, you may be sure that ammonia still exists in the urine in a volatile state. This rule will also determine the quantity of muriatic acid to be added when it is used instead of the oil of vitriol. The necessary quantity of sulphuric acid, when the acids are as strong as those usually sold, will be found to be one-third less than that required of muriatic acid. We prefer sulphuric acid as a fixer of ammonia; the sulphate, in all the experiments on the subject that we know, has proved a more powerful fertiliser than the muriate of ammonia. Muriatic is quite as dangerous as sulphuric acid among ignorant workpeople. Unburnt gypsum contains rather less than one-half its weight of sulphuric acid; therefore, if you find that a certain weight of oil of vitriol fixes all the ammonia which it contains, you may be sure that double that weight of "powdered unburnt gypsum" would produce the same effect.

MANURES.—*G. Sherborn*.—The mixture you propose would be suitable, but the quantity you propose to apply to an acre appears to us too large; and do not drill it with the seed, but scatter it broadcast, and harrow it well in before sowing; the young plants will find it out soon enough. For the nature of gas-lime see answer to question on the subject in No. 2 of the *Agricultural Gazette*. Analyses of the matters you refer to are to be found in chemical works.

MANURING GRASS LAND.—*H. Bellaire*.—July or August is the best time for manuring Grass land, to be mown the next year. The autumnal rains wash it into the ground. We shall take the subject up at the proper time.

MASTER AND SERVANT.—*J. J.*—In England, the servant could complain to a justice of the peace, who could, if the servant proved that the *meat* was not of the kind usual and proper in such cases, discharge the servant from the service. The justice, however, could not make any specific order directing the master to supply better meat. The servant could also bring an action for breach of contract. We do not know what provision the Scotch law makes for such cases.

PIGEON DUNG.—*Marcenas*.—Mix this dung with plenty of fresh mould, and it will then remain safely till you are ready to apply it. Powdered gypsum added to the compost would still further hinder the escape of the volatile constituents of this manure.

SALT AND LIME.—*A Subscriber*.—We shall answer your question next week.

SPRD-WHEAT.—*A Subscriber* may sow Wheat now, if his land be dry. We have been sowing during several days of the past week. Red straw White Wheat and Shirreff's White are two excellent varieties, which, as far as our experience goes, are suitable either as winter or spring seed.

TILE MAKING MACHINES.—*S. A.*—Etheridge's machine is preferable to that of the Marquess of Tweeddale.

WASTE OF HOUSES.—*Anonymous*.—You must gather them together and take them to a bone mill. We know of no other way, unless you make a compost with them and ordinary farm-yard dung. Add dilute sulphuric acid, which will probably assist in decomposing them.

*** As usual many communications have been received too late for answering this week.

Markets.

SMITHFIELD, MONDAY, Jan. 15.—Per stone of 8 lbs.

Best Beasts, Herefords, &c.	3s 10 to 4s 2	Best Downs & Half breds	4s 0 to 4s 0
Best Short Horns	3 8 3 10	Best Long woolled	3 10 4 0
Second quality Beasts	3 2 3 6	Lambs and second quality	3 4 3 8
Calves	4 0 4 10	Pigs	3 4 4 4

NEWGATE.—Beasts, 2868; Sheep, 20,000; Calves, 69; Pigs, 280.

There being a larger supply, both of Beef and Mutton, to-day, the trade is heavier. The best quality of Beasts, however, are not at all plentiful, and are readily sold at the above quotations; and in some instances, but very rarely, the choicest things have made 4s 4d. The best Mutton is rather more plentiful to-day than of late, and suffers a decline in price—the most selling Downs not making more than 4s 6d, the same general price being 4s 4d for the very best. Good Calves are scarce, and Lambs are dear. The Pork trade is a little more cheerful.

FRIDAY, JAN. 19.

To-day there is very little alteration from Monday's quotations: Beef is 2 shade lower; Mutton continues about the same. There is a still shorter supply of good Calves, with an advance in price—the very best are readily sold at 4s 8d per stone, and in some few instances rather more than that is obtained. A slight improvement in Pigs.

NEWGATE.—Beasts, 2311; Sheep, 8010; Calves, 167; Pigs, 260.

61, West Smithfield.

POTATOES, Jan 14.

SOUTHWARK WATERSIDE, Jan. 13.—There have been but few arrivals since our last, yet the market continues sufficiently supplied with former arrivals, especially with York Reds; the inferior samples from that country go off heavily, but the best samples from all quarters meet with a ready sale. The weather during the past week continues remarkably fine and open for the season, and the Dutch markets are abundantly supplied with Vegetables selling unusually cheap; notwithstanding which our late quotations have been fully realised.—Prices as annexed:—

York Reds	70s to 80s	Kent and Essex Whites	80s 85s
Perth	60 65	— Middys	60 70
Early Devons	60 70	Wisbeach Kidneys	60 70
Cornish	65 70	— Whites and Blues	60 70

MARK LANE, FRIDAY, JANUARY 19.—The arrivals of English Wheat are quite sufficient, and Monday's carryover would, we should, be fully adequate; from Scotland, no intelligence; but Edinburgh Saturday's prices are depressed. Barley is dull, and the quotations do not give way. Malt dull. Beans unaltered. The Oat Trade continues in its usual quiet, with a fair sale.

HOMEWARD AND LAID.

COVENT GARDEN, Jan. 19.—The Market has been well supplied during the week, but trade is not brisk. Pine Apples are sufficient to meet the demand, they are selling at nearly the same prices as last week. Hothouse Grapes are scarce, but Portugals continue plentiful; they have not advanced since our last report. Apples continue equal to the demand, and are selling at from 3s. 6d. to 10s. per bushel. Among Pears a few of the Passe Colmar are still in the Market; No Pics Meuris is also to be met with, but these are becoming scarce. Oranges are plentiful, and Lemons are sufficient for the demand. Filberts are abundant. Vegetables in general have been pretty liberally supplied during the week. Cabbages are good and plentiful. are likewise Brussels Sprouts and Greens. Broccoli is rather scarce. Seakale and Rhubarb are plentiful, the latter in particular is very good and abundant. Parsley continues to bring nearly the same prices as last week. Asparagus has become rather scarce, it has also advanced in price since our last report. Endive is good and plentiful, and Shallots are abundant. Celery is sufficient to meet the demand, but is rather inferior in quality. Cut flowers are chiefly composed of Erica gracilis and hyemalis, Poinsettia pulcherrima, Bignonia venusta, Correa speciosa, Geneva zebrina, Lily of the Valley, Pelargoniums, Fuchsias, Cineraias, Chrysanthemums, Camellias, Azaleas, and Roses.

FRUITS.

Pine Apple, per lb., 4s to 7s	Red Capsicums, 4s to 6s
Grapes, hothouse, per lb., 8s to 9s	Almonds, per peck, 4s
— Portugal, per lb. 1s to 2s 6d	Sweet Almonds, per lb., 2s 6d to 3s
Apples, dessert, p bush 3s 6d to 10s	Nuts, Spanish, per bushel, 10s
— Kitchen, p bus 2s to 7s	— Brazil, 16s
Pears, per half-sieve, 2s 6d to 10s	— Filbert, 7s to 8s

Horse Radish, per bundle, 1s to 2s	Sadlery, per score, 2d to 3d
Radish, spring, p doz bunds, 1s	Green Mint 4d to 6d per bunch
Carrots, p doz bun, 2s 6d to 3s	Marjoram, green, p doz. bun. 1s 6d to 2s
Spinach, per sieve, 1s 6d to 2s	Chervil, per punnet, 3d to 6d
Leeks, per doz bun. 6d to 1s	Balsafy, per bundle, 1s to 1s 6d
Garlic, per lb 6d to 8d	Scorzonera, per bundle, 1s 6d

HOPS, FRIDAY, Jan 19.

We can quote no alteration in the Hop Market since last week. Prices are fully maintained, and the stock in offer very limited, at the following currency:—

Mid & East Kent Pocks	6l 0s to 10l 10s	Sussex Pockets	4l 0s to 6l 0s
Choice ditto	11 0	Choice ditto	8 10
Weald of Kent Pocks	6 0 6 10	Farnham	9 10 10 10
Choice ditto	7 0		

PATTENDEN & SAXBY, Hop Factors.

HAY, SMITHFIELD, JAN 19.

HAY, 3l 10s to 4l 10s | CLOVER, 3l 10s to 4l 15s | STRAW, 1l 4s to 1l 10s

For Load of 36 Trusses. JOHN CLOWES, Salesman.

WHITECHAPEL, JAN. 19

HAY	3l 10s to 5l	CLOVER	3l 12s to 4l 8s
— fine Upland, 4l 5s to 5l 15s		— fine, 4l 10s to 5l	

STRAW 1l 4s to 1l 10s

Supply short, and trade dull.

WOOL.—BRITISH, FRIDAY, Jan 19.

CONSIDERABLE excitement has existed in our Wool Market during the past week. Those houses who are generally speculative have bought freely at rather advanced rates. For our own part, we see nothing in the reports from the manufacturing districts to lead us to suppose that any material advance in price will be permanently maintained.

	per lb		per lb
Prices Current.			
Long woolled Wethers	1s 0d to 1s 1d	Southdown Hoggrtes	1s 0d to 1s 0d

NEWSPAPER OFFICE, 15, Coventry-street, Haymarket, London.—Established upwards of 40 years.

T. MURIE and SONS, Agents for the supply of the GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE, forward that and all the other London Newspapers in common use (of which may be had on application), with the strictest regularity to all parts of the Kingdom, and to the Colonies, free of postage; and by the Morning Mails if requisite. T. M. and Sons beg to state that they print the entire address of their Customers on the wrapper, when ordered for six months or longer.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 324, HOLBORN.

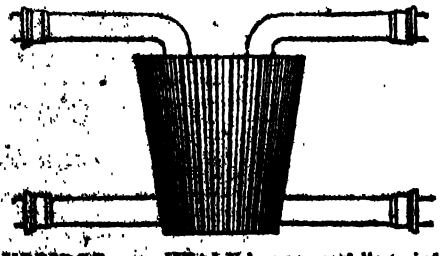
D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. Bailey also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 324, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. Bailey were the first to introduce metallic curvilinear Sashes to horticulturists, and can refer to the Conservatory erected in the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Greenhouses or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

RENDLE'S TANK SYSTEM OF HEATING.

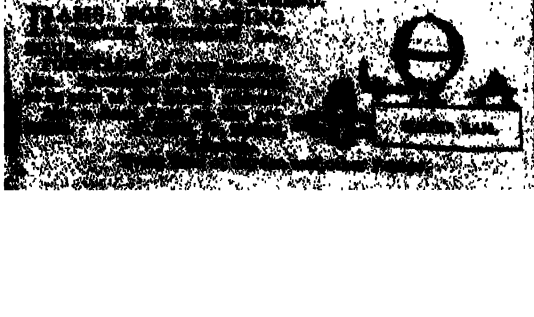


STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks which are ornamental in appearance can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of iron will be found cheaper than of any other material. Mr. Rendle, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

THE CONICAL HOT-WATER BOILERS, invented by J. Reesan, Esq., may be obtained of any size from JOHN SHEWEN, Ironmonger, &c., Sevenoaks, Kent.

J. Shewen having had every opportunity afforded him by an extensive practice to bring this apparatus to perfection, begs to offer it as most efficient and economical: it may be seen at Messrs. Chandler & Sons' Nursery, Vauxhall; Messrs. Loddiges', Hackney; Messrs. Henderson's, Pine Apple-place; Messrs. Veitch and Son's, Exeter; Mr. Pontey's, Plymouth; the Royal Botanical Society's Gardens, Regent's Park; and at the Gardens of the Horticultural Society of London. Considerable improvements have been effected since last season; particulars of which are in course of preparation.

IMPROVED PLAN OF [H]EATING.



J. WEEKS, Jun., and Co., Gloucester-place, Chelsea, beg to inform their friends in the Gardening Profession, that they will be happy to meet them at their Annual Dinner, on THURSDAY, Feb. 1. Those who will favour them with their company are requested to communicate as soon as possible.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural World, that they are quite ready to supply their new BOILER, of every size: they have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be safely relied upon; they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the rectangular and circular tank, which may be pronounced the perfection of a Tank Apparatus for Horticultural purposes, particularly for Grapery, Pinery, Orchid-house, Melon-pits, &c. &c. The arrangement is such that any gentleman or gardener may have the Tanks fixed under, so as to be put together with the greatest facility by the gardener, first sending a correct plan to the Plant-rooms. A Prospectus may be had detailing the prices, &c.

CHEAP FUEL for GREENHOUSES AND STOVES.

—Coke, the refuse of coal, as used by the Horticultural Society, to be had in large quantities at very reduced prices, at the Phœnix Gas Works, Bankside, Southwark.

GUANO ON SALE BY THE IMPORTERS, JOHN BOYD & Co., Wellington Chambers, London-Bridge, Borough.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. Lawes' Factory, Deptford Creek, price 7s. per cwt.

Phosphate of Potash	. . .	15s. per cwt.
,, Soda	. . .	12s. ,,
,, Magnesia	. . .	5s. ,,
,, Ammonia	. . .	1s. per lb.

GENUINE PERUVIAN & BOLIVIAN GUANO ON SALE, BY THE IMPORTERS, ANTONY GIBBS AND SONS, LONDON; GIBBS, BRIGHT, AND CO., LIVERPOOL AND BRISTOL. 47, Lime-st., Jan. 5, 1844.

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine, as imported.—Apply to Cotesworth, Powell, and Pryor, London; Edwards, Dannon, and Co., Liverpool; or William J. Myers and Co., Liverpool, the Importers.

POTTER'S GUANO.—Sir Robert Peel, the Earl of Zetland, and others, have used POTTER'S MANURE with the greatest success on almost every kind of crop and soil. Testimonials may be obtained by application, per post, at the Works, 28, Upper Fore-street, Lambeth, or of any of Mr. Potter's agents.—See also the Advertisement in this Paper of the 6th Jan., containing some of the Testimonials referred to.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with synopsis of mode of use, on applications to Mark Fothergill, 40, Upper Thames-street, London.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, in the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

Edward Purbrs, Secretary, 40, New Bridge Street.

LIQUID MANURE.

PUMPS of a Superior Construction, fixed and portable, for Liquid Manure. Garden Pumps, Hydraulic ditto, and Pumps for deep wells. Also Pumps for Ships, Barges, Tanners, Soap Boilers, Brewers, &c. Well-Digging and Boring executed. Benjamin Fowler (late George Turner), 69, Dorset-street, Fleet-street.

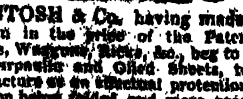
GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.

Noblemen, Gentlemen, and Gardeners will, by using this composition have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

Sold in Bottles, with directions for use, pints, 2s. 6d., quarts, 4s. 6d. each. One pint is sufficient to coat four Frames twice over, each Frame to be 8ft. by 3ft. 8in., or thereabouts. Prepared by George Whitney, Chemist, Shrewsbury. Gentlemen, Florists, and Merchants supplied by Mr. W. Bailey, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. Butler and Muckley, Covent Garden, where a sample of prepared calico may be seen; Mr. Watkinson, Market-place, Manchester; Page and Son, Southampton; T. and C. Whalley, Nurserymen, Liverpool.

Agents wanted for London and the country.

BY HER MAJESTY'S ROYAL LETTERS PATENT.



PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient "Protective Material" to Plants, and is now in use at the "Royal Horticultural Society's Gardens, Chiswick." It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade.

Thos. J. Craggon, 8, Ingram-court, Fenchurch-st., London.

SUPERIOR SUBSTITUTE FOR TARPAULIN, &c.

C. MACINTOSH & Co. having made a considerable reduction in the price of the Patent India Rubber Covers for Carts, Waggons, Ricks, &c., beg to call the attention of Users of Tarpaulin and Oiled Sheets, to the superiority of their manufacture as an effectual protection against wet, not liable to crack on being folded, and more economical than any other Waterproof cover.—64, York-street, Manchester, and 46 Cheapside, London.

DRAINING.—James Davis, Mathematical Instrument Maker, Darlington, begs to direct the attention of Agriculturists to every species of Drain Implement he has just constructed, viz., Pipe Moulds for Soles, Pipe Moulds for Collars, Pipe Moulds for Soles and Collars combined, Pipe Moulds for Tiles, Spades, Shovels, Pitchers, Paring Shares, or the pro-[illegible] Drain Tile Moulds, &c. &c. Any of the above can be had in a few days from the receipt of order, at the following prices, or at such other prices as may be desired. The [illegible]

NEW FARMERS' NEWSPAPER.

THE time has come when Landlords and Tenants, large Farmers and small, must devote their anxious attention to improved cultivation—when, in the words of Sir Robert Peel, "*All must learn how, in the shortest time, and at the least expense, to produce the greatest quantity of food, vegetable or animal, without permanent injury to the land.*" To accomplish this, no means can prove effectual as that which brings the results of Experience and Science before every man, in a cheap form. For this purpose THE AGRICULTURAL GAZETTE is established.

The Proprietors are aware of the difficulties of dealing with the many details of cultivation, without an acquaintance with circumstances, often as varying as places. They condemn the idea of conducting farming operations upon one invariable plan; and, while they welcome science as the best auxiliary of practice, they regard crude speculations as the most dangerous of delusions. But, they also feel that in Agriculture, as in all other arts, there are general principles upon which successful farming must depend; that there are practical errors which no local circumstances can justify; in short, that there is room for improvement, even in those branches which are best understood. No one man can be competent to deal with the multifarious questions affecting husbandry, and the duty of the Editor of such a Paper as THE AGRICULTURAL GAZETTE, is to make known the knowledge of all. It is to practical Farmers that the Proprietors trust for the means of carrying out their views, and not to the talents of any individual. While, therefore, they state that the Editor of THE AGRICULTURAL GAZETTE is a gentleman well acquainted with the best kind of Farming, in which he is actively engaged, they feel it to be of far more importance to announce the promise of assistance received from the landed and farming interest generally, especially of those whose names they are permitted to mention:—

The Right. Hon. the Earl Spencer, President of the Royal Agricultural Society of England.

The Right Hon. the Earl of Ducie, Vice-President of the Royal Agricultural Society of England

Mr. E. Beck, Rougham, Norfolk.
&c. &c. &c.

The Practice of Agriculture—its Science—Animal and Vegetable Physiology—Improvements in Implements—better modes of Husbandry—results of well-conducted experimental Farming—Growth and Rotation of Crops—Stock—Drainage—Irrigation—Foresting—Road-making—Farm-Buildings—Labourers—in short, whatever affects the beneficial employment of capital in land—will form topics of consideration. Reports will be given of the English, Scotch, and Irish Agricultural Societies—London Market Prices of Corn, Hay, and Cattle, and the Weekly Averages. Replies to questions connected with the object of the Paper will also be furnished weekly.

Considering the union which exists between Horticulture and Agriculture, it has been thought advisable to make THE AGRICULTURAL GAZETTE an addition to the GARDENERS' CHRONICLE, edited by DR. LINDLEY, and so extensively known; but that there may be ample room for discussion, that Paper *has been increased one-half in size without additional charge*—thus Twenty four Columns will be occupied, as at present, by Horticulture, and Twenty-four by the General News of the Week, whilst

Twenty-four Columns will be devoted to Agriculture.

This day, therefore, January 20th, is published, price SIXPENCE, stamped to go free by post, the THIRD NUMBER *of*

THE GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE:

A Weekly Record of Rural Economy and General News.

THE HORTICULTURAL PART EDITED BY PROFESSOR LINDLEY.

THE principle on which the Gardening part of this Paper is conducted is to make it a weekly record of everything that bears upon Horticulture, Floriculture, Arboriculture, or Garden Botany, and such Natural History as has a relation to Gardening, with Notices and Criticisms of all works on such subjects. Connected with this part are WEEKLY CALENDARS OF GARDENING OPERATIONS, given in detail, and adapted to the objects of persons in every station of life; so that the Cottager with a few rods of ground before his door, the Amateur who has only a greenhouse, and the Manager of extensive gardens, are alike informed of the routine of operations which the varying seasons render necessary. It moreover contains reports of Horticultural Exhibitions and Proceedings—Notices of Novelties and Improvements—in short, everything that can tend to advance the profession, benefit the condition of the workman, or conduce to the pleasure of his employer; accompanied with Woodcuts, whenever the matter treated of requires that mode of illustration.

To this Farming, as explained above, is now added.

Lastly, that description of domestic and political News is introduced which is usually found in a Weekly Newspaper. It is unnecessary to dwell on this head further than to say that the Proprietors do not range themselves under the banners of any party; their earnest endeavours are to make THE GARDENERS' CHRONICLE a full and comprehensive *Record of Facts* only—a NEWSPAPER in the true sense of the word—leaving the reader to form his own opinions; their object being elucidation of the laws of Nature, not of man. The reader is thus furnished, IN ADDITION TO THE PECULIAR FEATURES OF THE JOURNAL, with such information concerning the events of the day as supersedes the necessity of his providing himself with any other Weekly Paper.

The Proprietors are happy to announce that the following distinguished Botanists, Florists, and Practical Gardeners have already enriched the GARDENERS' CHRONICLE by their communications:—

The Hon. and Very Rev. W. Herbert, Dean of Manchester
The Hon. and Rev. Charles Bathurst
Hon. W. Fox Strangways
Sir Oswald Mosley, Bart.
Sir W. J. Hooker, F.R.S., Royal Gardens, Kew
Dr. Harris
Dr. Horner, Hull
Dr. Lankester, F.L.S.
Dr. Neil, Canon Mills
Rev. J. M. Berkeley
Capt. Widdrington, F.R.S.
Professor Morren, Liege
A. Ainger, Esq.
G. Barker, Esq., Birmingham
E. Barnard, Esq., F.R.S.

GARDENERS' BENEVOLENT INSTITUTION —At a special General Meeting of the Subscribers to this Institution, held on THURSDAY, Jan 11, at the Crown and Anchor Tavern, for the special purpose of Electing TWO poor persons on the Pension List of this Charity, the following was the result of the Ballot, viz —

JAMES ANDERSON	aged 72		174 votes.
ANN POITER	62		140
ELIZABETH COLLYER	69		30
SAMUEL LAWOOD	65		22
JOHN BLAYLOCK	71		16

The Meeting then declared that JAMES ANDERSON and ANN POTTER, having the greatest number of votes were duly elected Pensioners of this Charity EDW R CUTLER, Sec

THE LATE MR LOUDON —A Public Meeting of the Friends of the late Mr LOUDON will be held in the large room of the Horticultural Society's Establishment, Regent-street, London early in February next, to consider the best means of extricating his Widow and Daughter from the difficulties into which they are placed by Mr LOUDON's sudden death

Notice will be given next week of the day of meeting, when it is hoped that noblemen and gentlemen who patronise Horticulture, and also all Gardeners and Nurserymen who are within a reasonable distance will attend

AT a very numerous MEETING of Tenant Farmers, of the Three Hundreds of Newport, in the County of Buckingham, held at the Swan Hotel, Newport Pagnell on the 10th day of January, 1844, for the purpose of forming an Association for the Protection of Agriculture,

Mr EDMUND GREAVES in the Chair

It was Resolved—First—That this Meeting participates in the now almost universal feeling of abhorrence excited by the false and insidious statements and opinions put forth by the Anti Corn Law League, a conspiracy whose aim is to obtain Free Trade in Corn, but to preserve the protection enjoyed by the manufacturer.

Second—That this Meeting is impressed with the conviction, that the protection afforded to Agriculture by the existing laws is not more than an equivalent for the burdens imposed upon the land—that Free Trade in Corn is a delusion which would reduce to a state of beggary and want all who have invested their capital in farming operations—bring desolation and misery on the Agricultural labourer—prove destructive to the landed interest of the country—materially injure the tradesman and merhanic, and ultimately involve in one common ruin all classes of society, including the blinded advocates of so infatuated a scheme

Third—That this Meeting pledges itself to adopt all constitutional measures for opposing the Anti-Corn Law League, and resisting any attempt to weaken the protection at present extended to Agricultural produce.

Fourth—That a Committee be appointed for carrying into effect the foregoing resolutions and to co operate with any Central Society which may be formed in the County or in London, in such manner as may be considered most beneficial and that such Committee be composed of the gentlemen whose names are attached to the requisition convening this meeting, with power to add to their numbers, five to form a quorum

Fifth—That a subscription be now raised and placed at the disposal of the Committee E GREAVES, Chairman

At a Meeting of the Committee, held at the Swan Hotel, Newport Pagnell, on the 19th of Jan., Mr Greaves in the Chair

It was Ordered—That the Resolutions of the meeting of the 10th instant be advertised.

It was Resolved—That every effort be made by the Committee to increase the funds of the Association, by soliciting subscriptions from the landowners, tenants, tradesmen, and others

That a petition to both Houses of Parliament, founded upon the resolutions of the 10th instant, be drawn up and submitted to the Committee at its next meeting

That W. Powell, of Newport Pagnell, Esq, be requested to accept the office of Honorary Secretary and Treasurer to the Association. E. GREAVES, Chairman

TO GENTLEMEN and AMATEUR FLORISTS.—As the return of spring is fast approaching so is the planting of this beautiful flower the RANUNCULUS A few hundred roots to be parted with (with names), and a single root of the very high coloured purple flower "Gulzos," will be included in each bunch at roots, the time of planting February and March —Apply, pre-paid, to Mr. EVANS, Farnham, Surrey, where may be seen, in the blooming season, in Mr. EVANS's Collection of PELARGONIUMS, some Seedlings and other specimens of this most delightful, still-improving flower.—Farnham, Surrey, Jan. 25.

FASTOLFF RASPBERRY.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN HIS GRACE THE DUKE OF RUTLAND THE MOST NOBLE THE MARQUIS OF AILSA THE EARL OF HARRINGTON THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT TORTON, LORD SONDES &c &c as well as by the HORTICULTURAL SOCIETY OF LONDON

YOUELL AND Co. have much pleasure in announcing they are now supplying fine Canes of the above highly valuable and much esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour.

Those to whom Y and Co sent it last season have expressed their high admiration of its superiority over all other varieties, and has been awarded several prizes at various Horticultural exhibitions during the season As a proof they have not exaggerated its excellent qualities, fruit was submitted to Dr LINDLEY (see *Gardeners' Chronicle* of the 22d July last, page 502), whose opinion of it is as follows —

"FASTOLFF RASPBERRY —We have received from Messrs YOUELL, of Great Yarmouth, fruit of the Fastolff Raspberry, and we find it merits all that has been stated in favour of its excellence The fruit that we have received is very large, obtusely conical, and of rich flavour far exceeding in this respect some other new and large varieties The plants bear abundantly and in long success on"

They also exhibited it on the 1st of August, 1843 before the London Horticultural Society 21, Regent street, to which a prize was awarded It would therefore be unnecessary for YOUELL and Co to recommend it more fully or with greater confidence, to the notice of the public, merely observing that it continues in high perfection throughout the autumnal months, and has maintained its superiority in the most unfavourable soils and situations, and requires no other than the ordinary treatment of the old varieties

Fine Canes are ready for delivery, and can be sent with safety to any part of the United Kingdom (on the receipt of a Post office order), upon the following terms —

Packages containing 100 Canes	£2	5s	0d
Do do 50 do	1	5	0
Do do 25 do	0	14	0

Package included

The usual discount to the Trade when not less than 200 are ordered

*** CAUTION Y and Co beg to call the attention of their friends and the Public in general to the fact that they have appointed no Agents in London for the sale of the above, and can not be held responsible for its being genuine, unless purchased direct from their Nursery

YOUELL'S TOBOLSK RHUBARB, Patronised by Her Most Gracious Majesty the QUEEN, and many of the Nobility, 12s per dozen —For particulars of which see their Advertisement of the 18th November

TWO NEW SEEDLING PICOTEES — "LADY ALICE LEE" 10s 6d, and "MRS BENTON," 21s 6d per pair —These two splendid Picotees were raised by the Rev J Burroughes, of Kingwood Lodge Norfolk, and kindly presented by that gentleman to Messrs YOUELL and Co, for particulars of which see their Advertisement in this Paper of the 16th of Sept

FINEST CARNATIONS AND PICOTEES

YOUELL AND CO beg to refer the readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation

Prices as follows —	£	s	d
12 pair of good show Sorts	1	4	0
12 ditto fine ditto .. .	1	10	0
25 ditto ditto .	3	0	0
12 ditto extra fine and very superior ditto	2	10	0
25 ditto ditto ditto	5	0	0

The selection being left to YOUELL and Co

FUCHSIAS

1 dozen of the newest and very best sorts ..	21s
1 dozen fine ditto	12s
1 dozen good show varieties	6s.

Sent by post, free, to any part of the United Kingdom

ARAUCARIA IMBRICATA.

YOUELL AND CO., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms —Fine 3 feet 1 year old plants 8 to 9 inches high, 10l per 100, or 30s per dozen —Great Yarmouth Nursery, Jan 21, 1844

FUCHSIA SEED

YOUELL AND CO beg to inform their Friends and the Public they have succeeded in saving a small quantity of the above from the very newest and best varieties, which they offer upon the following terms —

A packet containing 100 seeds	10s		
Do do 50 do	6s		

sent post free on the receipt of a Post office order Directions for sowing, &c will accompany each packet

This will form an admirable opportunity to those who intend competing for Seedling Prizes at the exhibitions of the present year The quantities being very limited, early application will be necessary —Great Yarmouth Nursery, Jan 28, 1844

The true Beechwood MELON, 2... Regent-street Also CUTHILL's ... scented Border CARNATION, rec... the best Border Carnation ever ... 12s per dozen

SEEDS, NEW AND TRUE.

MESSRS. SUTTON AND SONS respectfully acquaint those readers of the *Gardeners' Chronicle* who have not yet hitherto honoured them with their commands, that their grounds being situated at considerable distances from each other, and of different soils, they are enabled, by strict attention, to grow GARDEN SEEDS true to their kinds, and supply Seeds which they know to be new, thereby preventing disappointment in the crops. A great saving of expense will also be effected, and the most improved sorts insured by purchasing either of the undermentioned collections, which are selected according to Messrs. SUTTON'S actual knowledge of the comparative merits of each kind.

	£	s.	d.
No. 1.—*A complete Collection of new Kitchen garden Seeds, of very best kinds, being one year's supply for a first-rate establishment*	3	3	0
No. 2.—*A Collection containing all the kinds as the above, but in smaller quantities*	2	2	0
No. 3.—*A complete Collection, in quantities suitable for smaller Families*	1	1	0
No. 4.—100 *Ranunculuses, in 50 fine varieties, by name*	1	5	0
50 *ditto in 50 do. do.*	0	15	0

N.B.—Parcels delivered free of carriage to London, or to any part of the Great Western Railway within 60 miles of London.

For Gardeners and others who would prefer selecting the sorts of seeds themselves, S. & SONS have just published their annual Catalogue of new Kitchen-garden and Flower Seeds, which will be forwarded immediately, post paid.

*** Where a reference is given payment need not be made for twelve months, which will afford ample opportunity for proving the excellence of the Seeds.—Reading Nursery, Berks, Jan. 2d.

DAHLIAS.

J. KEYNES, FLORIST, Salisbury.—"STANDARD OF PERFECTION," (Keynes).—The finest self-coloured Dahlia in the world! gained the 1st class prizes at Stonehenge, Windsor, Kingston, Surrey Zoological Gardens, and Crown and Anchor, Stockwell; also the 1st prize specimens at Stonehenge Floricultural Society, Stockwell. "It is as round as any Dahlia in cultivation; as complete an unbroken circle as could be drawn with the compasses; and as globular in front as possible. It is symmetrical to a hair, and as double as a Ranunculus. It is so remarkable as to be instantly recognised among a thousand. Colour, deep crimson. It is the flower of the season, and must be had."—*Gardeners' Gazette*, Oct. 14. "The best-grown flower we ever saw, without exception, every requisite to meet the taste of a connoisseur being complied with; good colour, a honeycomb, regularity of growth and disposition in the leaves, and above all, as complete a rotundity of shape as if it had been cast in a mould."—*Salisbury Herald*, Sept. 3, 1843. Plants in May, 1844, 12*s.* 6*d.* "Orange Superb," (Dodd's) first-rate show-flower, 10*s.* 6*d.* "The specimen sent would grace any stand."—Glenny. "Emma Noke," (Dowding's) bluish white, extra fine, indispensable to a first rate stand, 10*s.* 6*d.* Catalogues containing all the fine old varieties and new flowers for the season may be had on application.—Salisbury, Jan. 10, 1844.

DWARF CHERRIES GRAFTED ON THE PRUNUS MAHALEB, or PERFUMED CHERRY.

T. RIVERS, JUN., begs to offer the following sorts of CHERRIES, grafted on the above Stock, Root-pruned, and admirably adapted for potting, for forcing, or for forming Dwarf pyramidal Trees, to be protected by nets, 2*s* 6*d*. each:—

Arch, or Holman's Duke	Early Amber Heart (Rivers's)
May Duke	Florence
Royal Duke	Knight's Early Black
Late Duke	Imperial Morello
Biggareau	Black Tartarian
Black Eagle	Tradescant's Black
Belle de Choisy	Waterloo
Kiton	Werder's Black Heart.

The following Ornamental Standard Trees for Lawns are also offered:—

	s.	d.	each.	s.	d.
American Weeping Willow, 8ft.	5	6	Robinia macrophylla, or grandiflora, 6ft.	3	6
Cytisus elongatus (pendulous), 5ft.	2	6	*Yellow Broom, 5ft.	2	6
Cytisus purpureus (do.), 5ft	2	6	Double Dwarf Almond, 4ft. to 5ft.	2	6
Cytisus purpureus, flora alba, 5ft.	3	6	Siberian Almond, 4ft. to 5ft.	2	6
Cytisus pigricans, 5ft.	3	6	White-flowering Dwarf Almond, 4ft. to 5ft.	2	6
Cytisus falcatus, 5ft.	2	6	Dbld. flowering Peach, 5ft	1	6
Genista anxantica, 5ft.	2	6	Weeping Laburnum, 6ft	2	6
White Portugal Broom, 5ft	2	6	Eagle's claw Maple, 6ft.	1	6
Double Yellow Broom, 5ft	2	6	Lilac, rubra grandiflora fine plants, 6ft.	2	6
Robinia hispida major	3	6	Lilac, Charles X., do., 5ft	2	6

Female Plants (the fruit-bearing plants) of the Shepherdia argentea, or Buffalo Berry, recently imported from America, 2*s.* 6*d.* each. "Its fruit, which is much relished in America, is about the size of the Red Currant, much richer in the taste, and forms one continued cluster on every branch and twig."—*Loudon.*

Carriage of all Packages paid to London.

Those marked * are grafted on the Laburnum.

Bawbridgeworth, Jan. 25, 1844.

ANEMONES AND RANUNCULUSES.—The entire Stock of an Amateur Florist, who has spared no expense in procuring the finest sorts, but whose garden having been sold for building purposes, is compelled to part with them, and offers them on the following terms:—

RANUNCULUSES.

100 Roots, finest sorts, double, named flowers	21*s.*
50 extra extra ditto	15*s.*
100 fine ditto in mixture	8*s.*
100 ditto, second quality	5*s.*
50 Tyso's best semi-double ditto for seed	4*s.*
Packets of 100 seeds saved last year	1*s.* 6*d.*

Any of the above will be sent post paid on receiving a remittance by Post-office order, or letter-stamps to the amount wanted.

ANEMONES.

100 Splendid, named, double flowers	21*s.*
50 extra fine ditto	12*s.*
100 fine ditto in mixture	7*s.*
50 fine scarlet ditto in mixtures	8*s.*
Packets of seeds, each	1*s.*

Apply to S. G. LEES, Wine-merchant, Dundee.

SHOW DAHLIAS.

W. R. WHALES' SEEDLING DAHLIAS for 1844, to be sent out in May, at 10*s.* 6*d.* each.

PARAGON.—A splendid crimson scarlet, of good substance and outline, brilliant contour, and well cupped; an exquisite show variety; warranted to the description given of it; height 3 ft.; splendid habit.

SECOND CRIMSON PERFECTION.—A flower of great substance, nearly 20 petals deep; well cupped, rising centre, constant; first-rate habit; height, 4 ft. Early orders are necessary to procure this variety, being only true ground roots. Price 10*s.* 6*d.*

MARY.—A fancy border variety, white, margined with rose-pink; an abundant bloomer, and constant; occasionally a show flower; shape and habit of Keeling's Prince of Wales; height, 3 ft. Price 5*s.*—Elvet, near Hungerford, Berks, Jan. 25, 1844.

EARLY PEAS, &c.—HENRY D. CORMACK, SURREYMAN, &c., begs to inform the readers of the *Gardeners' Chronicle* that they can be supplied with the following Early and Prolific Varieties, viz.: Cormack's Prince Albert, British Queen and Early Kent Peas; Taylor's Improved Windsor, and Johnson's Wonderful Bean; Manchester Red and Seymour's White Celery; Wilmot's Long and Hamilton's Cucumber, &c., with every other variety of Horticultural and Agricultural Seeds, at his Wholesale and Retail Seed Warehouse, 166, Deansgate, Manchester.

DEATH OF MR. LOUDON.

THE SUDDEN DEATH OF Mr. LOUDON has involved his family in the deepest distress in every sense of the word; for although he laboured almost incessantly, nearly day and night, for the space of forty years, and his works had an extensive sale—yet, from the circumstance of his being an invalid for years, and the expensive nature of the illustrations to his Works, he died considerably indebted to the Printers and Engravers; the greater part of this debt was incurred in producing the most valuable, perhaps, of all Mr. Loudon's Works, namely, the "Arboretum Britannicum" a work which alone is sufficient to stamp his fame as an author.

After much consideration, it was decided that the best means of providing for his family (and a means, too, strictly in keeping with the independent spirit which characterised the life of Mr. Loudon, would be by promoting the sale of his truly valuable Publications. There is a large stock on hand of the following Works, the sale of which would extricate the family from their present embarrassed state, by enabling Mrs. Loudon to discharge the debt, and reserve the copyrights in her own hands as a means of future support; and it is earnestly hoped that every person who respects the memory of the late Mr. Loudon, will exert himself by soliciting his friends to become subscribers for the Publications enumerated below:—

Published in July, 1838, Price 10*l.*, cloth lettered,

THE ARBORETUM ET FRUTICETUM BRITANNICUM;

In Eight volumes: Four of Letterpress illustrated by above 2560 Engravings, and Four of octavo and quarto Plates.

Just published, complete in One Volume, Price 2*l.* 10*s.*, and in Ten Parts at 5*s.* each,

AN ENCYCLOPÆDIA OF TREES AND SHRUBS;

Being the ARBORETUM ET FRUTICETUM BRITANNICUM ABRIDGED: for the Use of Nurserymen, Gardeners, and Foresters.

Published October 1, 1839, in One Volume, octavo, with upwards of 250 Engravings, Price 1*l.* 10*s.*, and 2*l.* 5*s.*, coloured,

REPTON'S LANDSCAPE-GARDENING;

Being the whole Works on Landscape Gardening and Landscape-Architecture of the late HUMPHRY REPTON, Esq.; with a Biographical Notice, and Notes by J. C. LOUDON, F.L.S., &c.

Published August 1, 1838, in One Volume, octavo, numerous Engravings, Price 20*s.*,

THE SUBURBAN GARDENER AND VILLA COMPANION;

Comprising the Choice of a Suburban or Villa Residence, or of a Situation on which to form one; the Arrangement and Furnishing of the House; and the Laying-out, Planting, and general Management of the Garden and Grounds; the whole adapted for Grounds from One Perch to Fifty Acres and upwards in Extent; and intended for the Instruction of those who know little of Gardening and Rural Affairs.

Published November 1, 1842, in One Volume, octavo, with upwards of 300 Engravings, Price 10*s.*

THE SUBURBAN HORTICULTURIST;

Or, an Attempt to teach the Science of Horticulture, and the Management of the Fruit, Kitchen, and Forcing Gardens, to Persons who have had no previous Knowledge or Experience in these Departments.

THE GARDENER'S MAGAZINE;

Any Number or Volume published subsequently to 1834 may be purchased separately. The Second Series, consisting of Six Volumes, from 1835 to 1840 inclusive, for 6*l.* 8*s.* 6*d.*; for 1841, 1*l.* 1*s.* 6*d.*; for 1842, 1*l.* 2*s.*; or the third Series complete in 3 vols., 9*l.*

By a Post Office order being sent to Mrs. Loudon, Bayswater, London, any of Mr. Loudon's works will be forwarded in the monthly parcel of any local Bookseller; or through any Nurseryman or Seedsman in the neighbourhood of London. A list of the subscribers' names will appear weekly in the *Gardeners' Chronicle*.

A Public Meeting for the benevolent purpose of promoting the sale of these works will be held in the rooms of the Horticultural Society, Regent-street, London, by the kind permission of the Council, early in February, (notice of the day and other particulars will be advertized in the *Times*, *Morning Chronicle*, *Athenæum*, and *Gardeners' Chronicle* of next week) when it is hoped all persons taking an interest in Gardening, who are within a reasonable distance, will attend.

On the 1st December, 1843, exactly a fortnight previous to Mr. Loudon's lamented death, he published the following statement:—

"The *Arboretum Britannicum* was got up between the years 1833 and 1838, and published on Mr. Loudon's own account, at an expense of upwards of 10,000*l.*; the greater part of this sum was owing at the completion of the work, but it sold so well, till the late depression of the book trade in 1841, that only about 2,000*l.* of the debt remained to be paid off at the end of that year. It is, however, necessary to observe that this large proportion of the debt was not paid off solely by the produce of the *Arboretum*, but in part by the profits of Mr. Loudon's other literary property, consisting of thirteen different publications, (enumerated below), all of which stand pledged in the hands of his publishers, Messrs. Longman, for the debt on the *Arboretum*. This debt, at the present time, amounts to about 2,400*l.*; and hence, if 350 additional subscribers could be got, the debt would be at once liquidated, the works pledged for it set free, and Mr. Loudon or his family would enjoy the whole produce of his literary property.*

"This Appeal would never have been made, had not Mr. Loudon, who has been an invalid for several years, been lately seized with an inflammation of the lungs, terminating in chronic bronchites, which, even if the disease should be considerably alleviated, will effectually prevent him from any longer pursuing his profession of landscape-gardener, on the produce of which profession, and on the literary labours of Mrs. Loudon, he has entirely depended for his income, since his literary property was pledged for the *Arboretum*. Under these circumstances Mr. Loudon feels himself justified in taking this mode of soliciting additional Subscribers to the *Arboretum*, and in begging his Friends and Patrons throughout the country to assist him in obtaining them.

"The *Arboretum* has been spoken of in the highest terms in all the principal Reviews of Europe, and in the Botanical Periodicals of North America. The *Quarterly Review* says:—

"'This book is one of solid value, worthy of a place in the Library of every landed gentleman, as well as of every student of Botanical, Arboricultural, and Horticultural science . . . Let us warmly congratulate Mr. Loudon on having finished his Herculean task; a task which few men, except himself, would have had the courage to begin, and still fewer the perseverance to complete. The *Arboretum Britannicum* is complete in its kind, and it must become a standard book of reference on all subjects connected with trees.'—Oct. 1838."

The following Ladies, Noblemen, and Gentlemen, who already possess the work, on being applied to, have kindly permitted their names to be published as approving of the *Arboretum*, and of this Address to the Public:—

The Right Honourable LADY ROLLE	The EARL of LOVELACE	Capt. WIDDRINGTON, R.N.
Mrs. LAWRENCE, of Studley Royal	VISCOUNT COMBERMERE	JOSEPH STRUTT, Esq., Derby
The DUKE of NORTHUMBERLAND	The BISHOP of WINCHESTER	GEORGE CRANSTOUN, Esq.
The DUKE of DEVONSHIRE	LORD MONTEAGLE	L. W. DILLWYN, Esq., Sketty Hall
The DUKE of BUCCLEUCH	Sir JOHN TREVELYAN	J. T. BROOKS, Esq., Flitwick House
The DUKE of SUTHERLAND	Sir THOS. DYKE ACKLAND	GREGORY GREGORY, Esq., Harlaxton Manor
The MARQUESS of NORTHAMPTON	Sir H. E. BUNBURY	W. R. BAKER, Esq., Bayfordbury
The EARL of SHREWSBURY	Sir CHARLES LEMON	P. J. SELBY, Esq., Twizell House
The EARL of ESSEX	Sir OSWALD MOSLEY	PROF. HENSLOW
The EARL of ABERDEEN	Sir WILLIAM JARDINE	PROF. LINDLEY
The EARL of HARRINGTON	Sir W. J. HOOKER	PROF. ROYLE
The EARL FITZWILLIAM	The Rev. J. MITFORD	DR. NEILL
The EARL of RADNOR	The Rev. M. J. BERKELEY	
The EARL of RIPON	The Rev. W. T. BREE	

* It may be thought from the well-known extensive sale, for the last 20 years, of Mr. Loudon's Publications that he ought now to be independent: in consequence of too intense application while compiling the *Encyclopædia of Gardening*, Mr. Loudon fell into ill health in 1821, which obliged him ultimately to have his right arm amputated, his left hand being at the same time so much injured as to leave him with only the partial use of two fingers, and his left knee being anchylosed. In consequence of these bodily infirmities, Mr. Loudon has been obliged to keep an amanuensis and a draughtsman for the last twenty years, and also, during the greater part of that time, a servant to act as valet. Had it not been for the expenses thus incurred, and for others arising from the same source, Mr. Loudon might have been now independent, even without his literary property. This explanation is due to those who are ignorant of Mr. Loudon's personal character.

This Appeal has been most liberally responded to, and in consequence of it copies of Mr. Loudon's Works have been sold to the different Ladies, Noblemen, Gentlemen, Nurserymen, and Gardeners, whose names are included in the following list:—The names are given in the order in which the copies were ordered.

ARBORETUM BRITANNICUM.—10*l.*

Joseph Strutt, Esq.; 2d subscription; 10 copies
Mrs. Lawrence, Studley Royal; 2d subscription
The Earl of Radnor
Lord Folkestone
The Proprietors of the *Gardeners' Chronicle*

HORTICULTURAL SOCIETY OF LONDON.—Notice is hereby given that the Exhibitions of Flowers an Fruit, in the Society's Garden, in the ensuing season, will tak place on the following Saturdays, viz., May 18, June 15, and Jul 13. In addition to the regulations already announced, it ha been resolved that the Judges be instructed, in making thei awards, to take into consideration, whether the Plants to b judged have been exhibited previously during the season. Fu information concerning these Exhibitions can be obtained upo application at 21, Regent-st.

IMPROVED PLAN OF [H]EATING.

J. WEEKS, Jun., and Co., Gloucester-place, Chelsea, beg to inform their friends in the Gardening Profession, that they will be happy to meet them at their Annual Dinner, on Thursday, Feb. 1. Those who will favour them with their company are requested to communicate as soon as possible.

The Gardeners' Chronicle.

SATURDAY, JANUARY 27, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Jan. 31	Society of Arts	8 P.M.
Friday, Feb. 2	Botanical	8 P.M.
Monday, Feb. 5	Entomological	8 P.M.
Tuesday, Feb. 6	Linnean	8 P.M.

THE term LANDSCAPE GARDENING has been adopted to designate a profession, the principles of which, though volumes have been written about it, are not fully understood. The purpose of the profession is to assist those who have little or no taste themselves, in so arranging plantations, and shrubberies, conducting roads of approach, forming rides and walks, placing buildings, &c., as to satisfy the taste of others who may have any in such things. This definition, homely as it may appear, is in reality the marrow of the matter, and at once declares that those who may adopt the profession must have the taste required, to such a degree as to induce confidence to be placed in them. Then comes the question—who is to judge of the qualifications of a Landscape Gardener? Of course, persons who have, at the least, as much taste as the professor. Hence, were a nobleman or gentleman admitting himself not to have sufficient taste of his own to enable him to dispense with the help of a Landscape Gardener, to require it, it may be asked—to whom should he apply for guidance to a skilful professor? It is common in requiring the character of a servant to apply to the master whom he had last served. It is evident, however, that in the case of a Landscape Gardener, we should not apply for information to the employer, because he has, by the very act of employment, declared himself unfit to give any opinion. If the nobleman or gentleman be requested to judge for himself by looking at what has been accomplished, this is absurd; because he has confessed himself to have no knowledge of such matters—no taste; and consequently to be unable to judge of any such work. Here, then, is a difficulty somewhat startling. In order, not indeed to get rid of it, which is no easy matter, but to explain its origin, it is necessary to dip a very little way into the philosophy of the thing; and as Nature is always willing to teach and expound everything that may puzzle us, if we ask her to do so in a proper manner, our shortest way to arrive at truth in all cases, is to knock at her door and make known our wants.

Admitted into her presence, and humbly requesting to be let into some of her secrets, she bids us look about us, and observe the emotions which appear to be excited by the same object in different individuals. We stand near an ancient and noble Oak. The first person who passes looks up and says—"That must be a very old tree—it is so very big; I should like to know when and by whom it was planted—some centuries ago, I doubt not." The next person passes on without taking any notice of the tree. The third stops—looks upward and all around, moving from spot to spot, his eyes broadly opened—"Magnificent!" is his exclamation. "What a noble trunk!—worthy to support so noble a head! How gracefully the giant-arms part from the stem—each in itself a tree! How finely the masses of rich foliage, catching the lights and deepening the shadows, wave into the outline! That is indeed a specimen for the painter!" The fourth also stops—looks knowingly—measures the trunk by embracing it, and observes—"Three fathoms round, six feet through, some 20 ft. without a break!—and there—what glorious knee-timber among the branches!—a good many loads, eh!—and bark—let me see,"—and thus he goes on his way, calculating the value of the timber and bark. Now which of these was the man of taste in reference to the tree? The answer to this question will be different from different persons. An antiquarian will vote for the first; an indifferent person for the second; an enthusiast for the third; and a timber merchant for the fourth. To account for this the vulgar say, every one has his own taste: very truly. *De gustibus non disputandum*, says the wiseacre who is not fond of discussion,—and he too speaks truly. Thus we find that no one denies the fact, that the same object excites different emotions in different individuals. It is the same with groups of objects, in respect to their relative positions among themselves and surrounding objects. Now, though we might enter at some length into the philosophy of these things, it would not be suitable to such an article as this. Indeed philosophers are not quite agreed about the causes of differences of taste. We, therefore, refer such of our readers who may feel inclined to study the subject, to two of the most recent works, Sir T. D. Lauder's edition of Price, and Sir G. S. Mackenzie's Review of the Association theory, in which he makes a strong appeal to matter of fact.—*Gr.*

IN our last Number appeared an advertisement announcing the intention, on the part of some friends of the late MR. LOUDON, of calling a public meeting early in February, to consider "the best means of extricating his widow and daughter from the difficulties in which they are placed by his sudden death." This is, we believe, the proper course to take, for the desultory attempts of individuals can never produce the effect which may be anticipated from the operations of a public meeting.

We hope much from this plan, for there is evidently an anxiety among the gardening public to do something substantially useful on the occasion. We have published a few letters on the subject—many more are lying before us; the Members of the Regent's Park Gardeners' Association have had a meeting, for the report of which we regret that we had no room; and Mr. Paxton has issued a circular appealing strongly to the friends of Horticulture for assistance.

As soon as arrangements for the proposed meeting are completed they will be advertised in our columns.

WE do not consider that it will be useless or uninteresting to explain a little in detail some of the prevailing theories and contrivances having regard to the BURNING OF COAL and other similar materials in ordinary furnaces; because, although such knowledge may be of little use in the management of any given apparatus, it may, nevertheless, enable many persons to form a better judgment than they would otherwise arrive at of the various new projects which are perpetually brought forward: at the same time, it must be confessed that the minute display of chemical, down even to atomic illustrations, which are occasionally brought to bear on this subject, and the extreme nicety with which the elements of combustion are proposed to be balanced and adjusted, are somewhat out of place, when it is recollected that these refinements are spoken of in reference to an operation which undergoes immense changes, while the mechanical appliances remain unaltered. The furnaces to which these remarks apply have, among other causes of change, to be fed at long intervals, presenting, at one time, a dense mass of black coal, and at another, a heap of glowing cinders—a change of circumstance, which, independent of changes in the character of the coal and in the state of the air, must cause a very great change in the chemical action of the two periods, and must require equally great modifications in the admission and distribution of air, to render available the extreme accuracy which is professedly aimed at in the previous calculations.

This last remark, it is true, would not apply in full force to those furnaces which have revolving, or rolling, or oscillating, or otherwise movable grates, and which are fed at such short intervals and with such infinitesimal doses, that they may be said to receive a constant stream of coal. These costly and complicated contrivances seem, however, too troublesome or too expensive even for steam-engines, where there is power to work them and constant attendance to keep them in order; they may therefore be safely dismissed as hopelessly inapplicable to horticultural purposes—and without much regret, since they afford no proof that even they overcome the difficulty formerly alluded to, arising from the essential non-inflammability of some portion of the earlier products of distillation; nor do they attempt to meet the second great objection to ordinary furnaces, which will be presently explained, and which, if it exist as asserted, is the largest in pecuniary amount, though it may be the smallest in annoyance. There arises, it is admitted, but little visible smoke from some of these ingeniously-constructed furnaces; but that may be accounted for by the extremely small quantity of fuel supplied at one time. The complete absence of visible smoke is, however, no proof of complete combustion, as it is well known that there may exist a considerable escape of fuel in the form of transparent vapour.

Before, therefore, we quit this part of the subject, it may be stated, that, since it is out of the question to expect complete combustion, or to prevent the escape of very disagreeable matters from the burning of mineral coal, it will always be expedient to keep the chimneys as far removed as possible from an ornamental garden or conservatory, and this may be accomplished in at least two ways, employing either or both. The first method is to convey the smoke-flue from the furnace in an underground channel; and the second is to convey the hot water or steam in a heat-tight tube, which may be either above or below the earth. Either of these means may be used under ordinary circumstances to the extent of an hundred feet, making it therefore easy to remove a chimney two hundred feet from the place where its effects are to be produced.

Even this distance would not, in many instances, sufficiently remove the objectionable matters, and they are besides liable to be returned by the wind: it is still desirable, therefore, as a matter of luxury, as well as one of economy, to consume the coal in the best possible manner, and this will lead us to consider the matter somewhat minutely, as it is only by ascending to first principles that a judgment can be formed of the claims to philosophical accuracy and excellence which are advanced by some of the more recent candidates for public approbation.

The regulated admission of air, which is at present the favourite mode of improving a furnace, will first demand notice, and we cannot enter on this subject without reference to that invention, which has, perhaps, obtained the greatest share of notoriety, and which has elicited very favourable opinions from many persons whose names command respect. The invention we allude to is that which is secured by patent to Mr. Charles Wye Williams, and of which certainly all Horticulturists should avail themselves, if it possess but half the merit ascribed to it; and if it can be obtained on terms commensurate with the comparatively small consumption of fuel required for Horticultural purposes.

The description of this invention we must give in a future paper, together with an abstract of the principles on which it is founded.—*A.*

BEES.—No. IV.

(Continued from page 27.)

I shall now endeavour to ascertain the most profitable mode of augmenting hives. Within 20 miles of London, and, I apprehend, in many other parts of England, honey is seldom used by common trades'-people but as a medicine. In many parts of Scotland it is otherwise used: there, like butter, it is spread on bread and taken at tea. Hence, run-honey is dearer there than here, though honey-comb is not. In Scotland, where honey-comb (in small and neatly-made hives or boxes) is not sold for double the price of run-honey, eking, that is, raising the hives three or four inches with parts of old hives, is the more profitable system; for the Bees have not only more room to work, but also more comb to breed in, than they have when crown boxes are used. But about London, where honey-comb may be, I apprehend, sold for 2*s.* or 2*s.* 6*d.* a pound, the crown-box mode ought to be adopted. Honey, as well as honey-comb, is obtained when small boxes are used. Mr. W. Pettigrew, at Carluke, informs me that he has "taken three small crown-skeps (small neatly-made straw-hives, in which honey-comb looks better, and is more saleable in the Glasgow market, if I don't forget, than in boxes,) from one of my top or first swarms of this year. The first, which contained 9¾lbs. of comb, was sold for 17*s.*; the second, 9 lbs., for 18*s.*; the third, contains 7 lbs., which I have not sold yet: and from the hive on which these were filled I got 37¼lbs. of honey." He did not say how much honey he obtained from the stock, or second swarm; but we here see that he has realised from the produce of one swarm a sum bordering upon, if not above, 4*l.* Where crown-skeps or boxes are used no virgin swarms ought to be taken, even though those swarms (erroneously called *virgin*) may be taken off at or before the beginning of July. In propitious years a second swarm or turn-out will fill a box. Large swarms will fill a box or skep that holds 15 or 20 lbs., without breeding in it; but a box that contains about 10 lbs. of comb is more saleable than a larger one. As soon as a box or skep is put on and pinned to a hive, make the Bees run up into it by blowing smoke into the hive. In order to be able to ascertain when a crown-skep is filled, there ought to be two peep-holes in it. In taking off a crown-skep it is necessary, first, to sever it from the hive with a bit of brass-wire, then raise it with wedges three-eighths of an inch, that the Bees may lick the honey out of the cells that are broken and bruised with the wire. When it has been two or three hours thus raised, it should be removed, and, if the season is not over, another put on. If a lady or gentleman should, about swarming time, send in an order for a box of comb weighing 8 or 10 lbs., put a first swarm into a second swarm-hive, and you will be able to meet the order in a short space of time. But it may be well for those whose hives are at present small to dispense with boxes till their hives are larger.—*A. Pettigrew, Wrotham Park, Middlesex.*

(To be continued.)

BOTTOM-HEATING AND NIGHT-COVERING.

THE matter of night-covering is closely connected with that of Bottom-heating; and it is strange that the great utility of mats on structures such as Pine-pits (possessing a permanent source of Bottom-heat within) has not long since pointed out the much greater necessity for such coverings on structures for very early forcing, that depend for their heat, in many cases, on a considerable surface of parching flues or pipes.

The chief hindrance to the adoption of coverings at certain seasons, and for certain purposes, has been the want of a material at once light, pliable, durable, and economical. Regarding the last, I am sure that the saving of fuel would, under good management, pay for the cost of material; and for the former qualities, I have no doubt that, could the attention of our manufacturers be fairly drawn to the subject, we should not be long without something to the purpose.

I do not mean here to assert that Night-coverings are

necessary to all structures, and at all seasons—by no means; I would merely wish to draw attention to what takes place in an early forcing-house (unprovided with Bottom-heat) on a severe night—say in the middle or end of January, and the case in hand, by way of illustration, an early Vinery, depending entirely on flues or piping. If the atmospheric moisture, which must be provided by some means, could be kept suspended without condensation at the roof, there would be little occasion to care, in my opinion, about the loss of 5 or even 10 degrees of heat, and the 65° or 70°, as recommended by mere prescription, might be allowed to sink quietly to 55° without any injury—nay, with, perhaps, a positive benefit.

But how is this to be accomplished without roof-coverings, with an outside thermometer of, say 20°, and an inside one of 65° or 70°? To maintain these punishing temperatures a very strong fire must be kept up, which, from rapidity of circulation, must force some 20 per cent. of heat out at the chimney-pot, and exercise, by means of scorching flues or pipes, a powerfully extractive process (if I may use such a term) on the leaves.

To be sure, we can provide such an abundant supply of atmospheric moisture as may compensate for the loss; but can it be supposed that continual distillation of this kind can afford as genial an atmosphere as one in which the gases from sweet fermenting materials are kept in suspension, and in which all such distillation is obviated by a night covering?

It may be fairly assumed, I conceive, that in consequence of the great disproportion which light bears to heat in these northern climes as compared with tropical ones, that we are by no means justified in attempting to imitate the extreme points to which vegetation is subjected in those climates. The general consequence is an impure atmosphere, which, in conjunction with the want of light before adverted to, produces many and serious evils; amongst which we may mention, first, long-jointed and of course imperfect wood; and, secondly, a dissipation of vital energies, leading ultimately to abortive results.

I have a Peach-house under my care, the night temperature of which has frequently, about the end of February, when the fruit was as large as Peas, been as low as 40°; and, so far from receiving injury, the fruit has been benefited by it, and, grown under those circumstances, has carried a medal six or seven years successively from the Horticultural Society of London.

As to the mode of obtaining bottom-heat, it appears to me that although the tank-system is destined to supersede the old modes of bottom-heat, (and as a general principle deservedly does so,) yet a little consideration is necessary before those enthusiastically inclined towards the new mode discard entirely the old process of fermenting materials. A question arises about the character of the tank covering with regard to the admission of so much moisture as may be necessary, and no more; and a second, more important still, whether the gases produced by fermenting matter can or ought to be entirely dispensed with.

I presume that the gaseous products of fermenting matter are a very different thing from the mere steam of water, which, although gaseous, is not so rich in constituents. Without chemical knowledge, every gardener knows that what is technically called "a sweet bottom-heat," such as a well-wrought Cucumber frame, is just the sort of place for certain quick-growing plants to make the most rapid advance in; therefore it seems to me to be something more than a mere question of heat and moisture.

The sweet bottom-heat of fermenting materials "well-wrought" approximates the conditions of moist tropical climates, about which I beg to quote Mr. Solly's remarks in "Rural Chemistry," (p. 368) which runs thus:—"In hot moist regions of the tropics, plants grow with far more rapidity, and vegetation is more vigorous, than in temperate regions. In tropical countries decay proceeds far more rapidly than it does in our own country; carbonic acid and ammonia, the food of plants, are produced in greater quantity than here, whilst, from the greater power of the sun, plants are able to assimilate more of those substances than they can in colder countries."

Something, therefore, yet remains to be done before we entirely resign the use of fermenting materials; perhaps the time is not distant when, from repeated analysis and extended physiological knowledge, we shall be able to impregnate the atmosphere of hot-houses with the necessary gases by a regular system.

As to plunging or planting out in a bed of fermenting materials, we acquire still further powers in combatting low temperature, leading ultimately, in-doors, to economy in fuel.

In confirmation of this I need only refer to the "Theory of Horticulture," (p. 105,) where, in a note at the bottom of that page, is fully shown how this principle, which is universal in Nature, or nearly so, acts; and which is amply borne out by facts in every-day practice. The frequent depression of atmospheric temperature out of doors, by winds and otherwise, must very frequently leave the bottom-heat much more than is commonly thought in advance of that of the atmosphere.

Great anxiety is manifested on all sides to obtain clear glass for hot-houses, and very properly; however, not so much pains is taken to keep it clean afterwards.

All pits and frames should be washed at least twice in the year, say February and October, as great benefit will arise therefrom.—*Robert Errington, Oulton.*

SEEDS OF GARDENING.—No. IV.

(*Concluded from p. 35.*)

But I must not on any account dismiss the tin box and the label so lightly, without adverting to its usefulness to lady gardeners, and indeed amateurs in general, who do not get their living by gardening, and are frequently not so familiar with some of its intricacies as (be more experienced veterans in the art; for in this I mean to bring the science, or, in other words, all that is known of gardening, to bear so closely upon the practice, that gardener amateur, or even apprentice, may sow seeds in the right sort of soil at the proper time of the year, and for the proper purpose, since every packet of seeds will be enveloped in the information necessary to rear them; for I have seen cases enough where better might have been expected of persons sowing such as Loasas and Convolvuluses, of very dissimilar habits, in such a way as showed that they thought all Loasas were tall twiners, and all Convolvuluses more or less similar; whilst it is notorious that in both genera there are species that grow only a foot high, mere tiny herbs, whilst others are giant twiners, requiring two or three fathoms of stick or string to support them. When I saw these sowed side by side, I thought, if there had been black letters on the seed-packets setting forth the character of each, things would have been far otherwise, leaving those who erred quite inexcusable.

Those who grow things properly will find the seed-packet cheap enough, and he who sows seeds not knowing what they are, and expects from them what nature never ordained, has "paid too dear for his whistle," and will find that seeds alone are useless and even too expensive, however cheap, without a system to grow them by. But some will, no doubt, ask how this very desirable information respecting all our most interesting garden-seeds is to be obtained? Gardening books abound with such information; but as no living man appears gifted with such extraordinary intellect as to be able to retain it so clearly and fully as to bring it to bear upon his practice at a moment's notice, and amid the bustle and toils of the day, I propose to save racking the brain unnecessarily; and more effectually to serve the purposes of gardening, to digest into the form of a label, and under the head "directions for use"—in plain English, a treatise on the character and culture of the contents of the packet. Mrs. London's "Book of Annuals" would give in simple, popular, and scientific terms the sort of information I speak of for Annuals; and so of other books for the culinary seeds, &c. But for the most part I have another plan, and that is a sure one, to come at the practical points:—the man that grows seeds, first flowers the plant and then fruits it; he, therefore, may know if he pleases more of it than the gardener, who only flowers it. If, therefore, the seed-grower would set forth in writing on the seed-packets the character and culture of them (a theme which must be familiar to him) instead of giving their good properties and details of their uses *viva voce* to the seed-buyer, the chain of information would be complete; it would come direct from the man who perfected the plant, flowered and fruited it, to the man who was about to commence more or less of the same process; and if seedsmen were only to buy seeds from such as knew what the nature and uses of the seeds were that they were selling, we should soon reform our seed-packets, and equal or surpass the men of Birmingham or Manchester in the beauty of our labels and the details of our manufacture; but this is not all in the systematical arrangement of seeds, for if it be necessary for the butler to have bins and a well-furnished pantry appropriate for his business, and the housekeeper to have ranges of shelves and drawers, and other stowage for her paraphernalia, each according to its kind, surely there is something more appropriate for valuable seeds than to be tossed in loose papers in the bottom of an old hamper, which I am sorry to see is too generally their locality. I would therefore arrange them in trays, each tray to be a drawer, and fit into slides forming a nest or chest, the top being a table or counter, the laboratory of the seed department. One tray would hold 200 separate packets of the size of the percussion-cap box, which holds 2 oz.; and this tray would only be 40 inches long and 20 wide: and, mark well, every packet would be open to view, and might be as easily opened and some seeds come at for sowing and the remainder secured as the grocer comes at his Congou Tea for the ready money customer and secures the remainder in his well-ordered canister.

Now, let any one put 200 papers of seeds, untied, in a drawer 40 inches by 20, and let him look them over once or twice to sow small moieties and replace the remainder, and see the result—the working of the medley; and if he has the bump of order in his head at all, he will thank any one to lend him a hand to set his seeds in order. Begging pardon for this lengthy document, which I could not abridge and render the meaning clear, I hope seeds may be respected, saved, preserved, and carefully distributed, and then our waste lands would wear a warm and wealthy aspect when the myriads of seeds of all kinds that are annually wasted should be gathered into barns and put forth to usury in the spring in the bank of Earth.—*A. Forsyth, Alton Towers.*

THE ROSE-GARDEN.—No. II.

(*Continued from page 36.*)

Securing a Supply of Buds.—It is necessary, at the commencement of the following observations, to remind the reader that *ex quovis ligno non fit Mercurius: Anglice,*—Good work will not spring from bad materials. Previous, then, to making any other preparations, it is desirable to secure a supply of buds against the time when they will be used, either by having the plants from which they are to be taken, in the garden of the operator, by promise from that of a friend, or by purchase from a nurseryman who can be relied upon. (It may be as well to remark here, that if either of the latter be the case, it will be well at the time of use to see that the shoots on which the buds are be quite fresh, or, if possible, to cut them on the spot.) If, however, the necessary supply cannot be obtained by any of these means, nothing remains but to buy a few plants for the purpose. In this case, fine ones should be secured, as small weak growers will produce few shoots fit for the purpose. If the plants to give the buds be on their own natural roots, it is necessary to see that they are planted as soon as they have lost their leaves in autumn, in order that they may get well settled before the spring; but if it be desired to secure a good supply, a strong-stemmed standard Rose or two should be purchased at a nursery, and such only chosen as have plenty of young wood, and are in health. By choosing them without reference to shape, and merely on account of the buds they are expected to yield in autumn, those may be obtained which have been rejected for a season or two by other buyers, and are vigorous and well-rooted. They should be planted with good mould round the roots in November, and care taken to remove any leaves there may be on the trees previous to planting. If well staked and trimmed, as subsequently directed, a more regular and certain supply of buds will be procured than in any other way; and, provided the trees be a little favoured, they may get over the injuries inflicted by removing their best shoots, especially if two or three buds be left at the base of each shoot thus removed.

Choice of Stocks.—The proper time to procure stocks is during the month of November; (the period, however, may be delayed until the 1st of February, but it is not desirable to do so, for plants procured and planted in Nov. will be found to produce much finer shoots than those planted later; the shoots upon them are also better placed, two rarely starting from the same eye, but springing from following knots, and are opposed to each other on the stock; and if three shoots push, they are in general from the three upper rings on the stock, and evenly triangular. November plants seem to accumulate their strength, and, as above mentioned, forming their buds at the nearest possible points to the extremity of the stock, start and continue their growth with unabating vigour, and at the end of May an unexperienced eye would at once discern the difference between a body of stocks entered in November and the same quantity placed in the ground in January or February, although an unequal strength in single plants might render the difference not so perceptible.

Four objects are gained by early planting; viz., large shoots—well-placed shoots, with reference to each other, both in proximity and position—the formation of a head as near the extremity of the stock as possible—and, on the whole, a more vigorous plant. Late plants, on the contrary, are uncertain as to the places where they will push; a part of the stock is frequently lost from this circumstance. A greater degree of trouble is incurred in removing useless shoots straggling about the stock: and the shoots which are eventually retained are faulty in one or more of these particulars, viz., of a more uneven growth, much smaller than is desirable in circumference, fewer in number, or backward in their growth.

Stocks, however, procured even so late as the 5th or 6th of April, will occasionally succeed, and nothing more is necessary than to send to the nearest wood-cutter, or the headsman of a farm, and desire them to make a collection either from the woods, or to save a supply when they grub up a hedge: in the former, many single plants will be procured; in the latter, most of those which spring from a clump-root. This latter is a matter of small importance, as the wild stock will flourish with hardly any root, and indeed often strike without a single fibre, although plants with fibrous roots are much to be preferred.

In all probability, following the directions received, all sorts of stocks would be brought as well as heights: although they differ both in size and sorts in different places; the red have the hardest and firmest wood, and have least pith; the smooth green are the easiest to bud on the stem, and the green and brown striped are between the two. Some sorts, as the red, do not take freely; but as budding should be done at a time when success is almost certain, this is a matter of less consequence than the appearance of the future tree; the clean, healthy, sizable stock, therefore, should be chosen without reference to the colour. If, however, there be large choice, the green, green and brown striped, and grey, are questionless the best, the red having a tendency to go off, especially when transplanted.

It is true that the size of the stem will continue to increase after grafting, but not in the same ratio as it would have done with a wild head; the free growers will, of course, increase it much more rapidly than delicate sorts, and if the roots are freed from rotten wood in planting and transplanting, and the shoots above well pruned, there is no fixing the size the stock will attain to.

(*To be continued.*)

ON THE CULTIVATION OF PERSIAN MELONS.

I SEND you a description of the house in which the Persian Melons lately exhibited to the Horticultural Society were grown (see p. 543 and 662). There is nothing novel or remarkable about it, and I should not have thought it sufficiently interesting for the pages of the *Chronicle*, but that I see a great diversity of opinion prevailing as to the best method of affording bottom-heat. One gardener advocates steaming the roots of plants over open troughs of hot water; another prefers a dry heat, obtained by lighting a fire beneath the bed; a third says that the open tank-system will not do for Melons, because the steam reduces the soil to the condition of mud; while a fourth asserts that the soil is then in the very best condition for the growth of these plants.

Amidst so many conflicting theories, all supported by experienced men, who I have no doubt could each in his own way obtain success, I think that descriptions of

structures already in use, and of the measure of success attained by them, may be serviceable in assisting the unpractised in the somewhat difficult task of deciding; and perhaps I may be able to show, that even those who have no means of obtaining bottom-heat need not despair of growing very good Persian Melons without it, provided they do not aim at having them too early.

The house, of which the accompanying cut is a section, was built in the spring of 1842, principally for a Melon-house; but it is found useful in the winter for forcing Pelargoniums, and in the early spring for Strawberries; to both which purposes it is well adapted, on account of its lightness, the trellis being at such times replaced by a portable stage. It is 28 feet long, and 15 feet wide, and is heated by means of a saddle-boiler, with four-inch pipes passing round the outside of the pit. These pipes are fitted with cast-iron troughs, for holding water, to regulate the moisture of the atmosphere. Beneath the pit is an arched chamber, *a*, along the front of which runs the flue, *b*, imparting a very slight degree of heat to the soil above, and also serving to heat a series of arches, *c*, which run along beneath the path, and are entered from a house in front, *d*, and which are used for forcing Rhubarb, &c. in the winter. I may also mention that the house in front is heated by the same boiler.

In the beginning of June, the house was cleared of Strawberries; it then underwent a thorough cleaning. The pit was next filled, by placing first about six inches of decayed dung and leaves, and upon this a compost consisting of one-half surface-soil of a pasture which had lain for twelve months, and one-half a mixture of turf, dung, and brick-rubbish, that had been thrown together for a Vine-border. The depth of the soil was about two feet. The trellis being then fixed, the arrangements were complete. On the 15th of June the plants were turned out, one in each light, and planted about six inches from the front of the pit. They grew most luxuriantly; only two shoots were allowed to go up the trellis beneath each light, and about three Melons were left to swell in the same space. By thus limiting the number of shoots, the leaves had plenty of room to expand, and I think I never saw finer foliage. The number of fruit was twenty-one, and the average weight about eight and a half pounds. The temperature of the house was kept to seventy-two degrees by fire-heat, and the heat of the bed never exceeded seventy-five degrees. As the moisture of the soil and atmosphere is of the greatest importance in bringing to perfection the Persian Melon, I may add, that I never allowed any syringing, or watering with a rose pot; but twice while they were growing the bed received a thorough watering. The depth of the soil, and its being of a nature to retain moisture, precluded the necessity of often watering. The troughs were kept full of water till the fruit began to ripen, when the atmosphere of the house was kept as dry as possible.

Although the soil in this house received a slight degree of heat from the flue beneath, we have Melons growing in two other places, and doing equally well, without bottom-heat at all; and everything has been obtained from a good soil of sufficient depth that could be desired or expected, from either open tanks or closed ones. One of these places is a low pit, where the soil is placed upon the drainage, with the exception of a thin layer (about 6 inches) of decayed leaves. The other place alluded to is a Fig-house, in which the plants grow in pits about 6 feet long and 2 feet wide. The Melon, for which a Banksian Medal was awarded me in August, [a very fine one indeed—*Ed.*] was grown entirely without bottom-heat. I do not mean to infer from this that bottom-heat is useless, on the contrary, for early crops of Melons I consider it indispensable.

The above is an account of the method pursued in this particular case—with what success those who saw the crop growing in July and August can judge. I shall now make a few general remarks on the soil, on watering, and stopping the plants.

It is of importance that the soil be as rough or lumpy as possible for the Melon, as I find that the roots delight to run among and cling to these lumps, as may readily be perceived by taking one of them up, when the roots will be seen spreading in every direction, and protruding through the surface. The compost I prefer, is one-year-old turf from an old pasture, a small portion of rotten dung, and some lumpy marl, with a little charcoal sprinkled among the marl previous to its being added to the compost. It should be 2 feet deep for the plants to root in, and if moderately dry at first, the fibres will be more numerous and healthy. Supposing things in a state of readiness to turn out the plants, they should be planted at the front of the pit, the leading shoot pinched out so as to leave two eyes, and a slight watering given to the plants to settle the soil round them. If the plants will do without water till the fruit is set, so much the better; as by this time the whole mass of compost will be occupied with fibres ready to supply much nourishment to the plants, and it may be imagined what rapid progress the fruit will make after the first thorough watering the compost receives; the water must be of the same temperature as the compost. At this time great attention should be paid to keeping the atmosphere of the house dry; or if the weather be dull, the proper organisation of the leaves will be prevented by the too great quantity of vapour from the newly-watered soil; to prevent this I place dry mats on the surface, and give a little extra air, keeping up the temperature by the hot-water pipes. During sunshine, the mats are removed to allow the surface to become dry again. By the time the fruit is half swelled, water may again be required,—it must be given as before, paying the same attention to the state of the atmosphere. This will probably suffice till the fruit is ripe; but if water should be again required, it should be given at the sides of the bed of soil, where the extremities of the roots will be, and so as to wet the surface as little as possible, as the atmosphere cannot now be kept too dry for the flavour of the fruit. I may here observe, that the best way to give water is to pour it from the spout of a pot without a rose, and as much between the lumps of soil as possible. In very hot weather the red spider will be troublesome, and I find it necessary to puff sulphur and snuff on the under-side of every leaf, which is easily done in our Melon-house, as the trellis is so much above the soil that a boy may get to nearly every leaf without touching them: this plan is much better than steaming and sprinkling for the Persian Melon.

I now come to the management of the shoots and leaves, which is a point of great importance, as, unless the leaves are allowed plenty of room, by retaining but few shoots and are kept green and healthy till the last, the fruit will not be good in flavour. My rule is to allow no more than two shoots to be taken up under each light, and no laterals allowed to grow except those on which the fruit are. When the shoots reach the top of the trellis they are stopped, in order to throw strength into the laterals, on which the young fruit will now be forming. When three of the most promising fruit are set, the rest should be cut away with the laterals, and the plants should be examined daily for some time, to see that not a leaf overlays another, and to pinch all laterals that appear.

The Hoosainee Melon may be known to be about ripe when a sweet juice exudes from the stalk near the fruit, which will generally happen in about thirteen or fourteen weeks from the time of planting out.—*C. Fleming, Trentham Garden.*

Home Correspondence.

Bees and Dutch Clover in New Zealand.—As "R." has applied directly to me respecting the cause which has produced the accession of Dutch Clover recently observed in New Zealand, I will reply to him in the best manner I can. I am inclined to think that the increased produce of Clover has been rather coincident than correlative to the introduction of honey-bees into the Colony, and that it has arisen from some change in the culture of the soil; as such changes are well known to be capable of producing such an effect. If a pasture-field be dressed with soap-maker's waste, or with a compost well imbued with lime, or with lime only, there will be a crop of Dutch Clover, though it had never appeared, or but scantily appeared before. Some attribute this to the land's being placed in a favourable state for the germination of Clover-seed, which had lain dormant in the earth, only awaiting the favourable circumstances referred to, to bring it forth. Others regard it as a parallel case to that afforded by the celebrated Mr. Crosse, who by means of electricity has brought into existence insects previously unknown, and as therefore militating against the doctrine of *omnia ab ovo*. It is a knotty point which I shall not presume to decide, but I hope the remarks I have made may call forth others from some of your intelligent correspondents.—*Edward Bevan, Esgair Evan, Newtown, Montgomeryshire.*

Culture of the Carrot.—Some gardeners imagine that old garden soils are not favourable to the growth of Carrots; but I have produced them in two old gardens, which for years had refused to produce them by the common modes of cultivation. The system I pursue is this: in autumn the ground is trenched to the depth of eighteen inches, in the bottom of each trench a little quick lime is sprinkled and forked up with the bottom; the surface remains quite rough until spring; previous to sowing, a little river-sand or sandy earth is spread over the surface, and dug in as deep as a common spade will do it. I then add a little more quick lime, and rake the surface level; the beds are then formed; drills are drawn in the usual way; the seeds, being mixed with river-sand, are then sown, and covered in with the back of a rake. The width of the drills varies according to the sorts; for small-growing kinds, such as the Early Horn, eight inches is about the width; for the Altringham, ten inches; and for the largest sorts one foot is not too much; and they are thinned out to about the same distances in the drills. Thinning is of the greatest importance: the allowing them to remain too thick is not unfrequently the cause of disease. By the above system, I produced last year on one hundred and twenty square yards nine cwt. of picked roots (varying in length from one foot to eighteen inches), one cwt. of small, and three cwt. of tops, all perfectly free from speck, the sort being the Altringham.—*P. Elliot.*

Cucumbers.—A correspondent, "P. Cope," informs us that at an obscure place in South Salop there was a Cucumber cut on the 3d of December, measuring 13 ins. in length, and 13 in. in diameter. He inquires if any of our correspondents have outdone this.

Oaks.—Seeing that you recommend Quercus sessiliflora, I shall be obliged by your stating under what circumstances, since it is considered very inferior timber. There is not, I believe, a neighbouring woodman here who is not aware of the extreme softness of the Durmast Oak when felled, or of its very fragile character when applied to any of those uses for which the tenacious properties of the Q. pedunculata are esteemed. The knowledge of this by the Commissioners of Woods and Forests induced their sending particular instructions to the late Mr. Turner (their then surveyor of the New Forest plantations), to cultivate only the Quercus pedunculata. These instructions were accompanied by drawings, which are, I believe, kept in the office of the present surveyor, Col. Thornhill, at New Park. My motive for addressing you is the endeavour to prevent any error that may be likely to accrue upon a subject of such importance as the cultivation of the proper sort of Oak for timber. I have for some years directed my own attention to this subject, and I should be very glad to possess any information that you may be able to afford. It is not many days since that the proprietor of an estate in the Forest directed my attention to a large tree of Q. sessiliflora upon his property at Minstead, saying, "There is a Q. sessiliflora, it is very brittle timber." This gentleman is a large possessor in the Forest, and is, perhaps, more conversant than many other persons with this subject. Contiguous to this property, and upon the open Forest, stands a large tree of Ostrya virginica (supposed to have been planted there by Lord Delaware); it has by many persons been considered an Elm, and branches of it in flower have often been shown as such. There are likewise two fine trees of Quercus alba near the same place, but they do not produce Acorns.—*Rufus, Lyndhurst.* [After having occupied so much space formerly with discussions concerning the popular prejudices against *Q. sessiliflora*, we must refer our correspondent to our Volumes for 1841 and 1842, especially the former. This is certain, that the wood of Q. sessiliflora is in no respect inferior to that of Q. pedunculata. Both are affected by soil, and are occasionally of bad quality. The name Durmast Oak is, apparently, applied in the New Forest to different plants, and therefore furnishes no evidence against Q. sessiliflora.]

Piping Carnations.—This has been successfully practised by removing the mould from a Tulip-bed, placing the leaves of the Tulips underneath, and passing the mould through a coarse riddle. The pipings stuck in this mould are covered with a hand-light, exposed fully to the sun; but in hot weather, in the evening, water is poured over the hand-light. It requires an active person to pick out worms and slugs. If the pipings are placed in a box, covered first with a bell-glass, which is to be exchanged for a small hand-glass, or a larger bell, as the pipings begin to grow, the boxes placed on a stage on a N. side of a tree, and the stage resting on feeders filled with lime-water, there is less trouble with insects, and the pipings will grow very well, but not so rapidly nor so strong as in the former method.—*O.*

Mildew.—I wish to add a few facts to those already stated with regard to mildew, and I hope to suggest a remedy. Having in my conservatory, which may vary in temperature from 38 deg. to 70 deg., an Aimée Vibert Rose, a Hymenée, Thé do., and a Microphylla do., extremely subject to the mildew, I began about a year ago to try a remedy which I think I must have met with in the *Gardeners' Chronicle*, viz., to water them with nitre dissolved in water. The effect is, Aimée Vibert is quite cured, and Hymenée, whose wood was almost destroyed by the disease, is totally free, and making beautiful young wood, the Microphylla, though much improved in health, has still a little of it left. I used 1 oz. nitre to 1 gallon of water (the best I could get at a chemist's), and about once in 10 days during the summer, and am just beginning again to do so. I should think if the Peach-trees were well syringed with the solution, taking care there should be enough to water the roots, it would be effectual there also. I tried sulphur without the least effect.—*Omega.*

On Summer-Pruning Fruit-trees.—In summer-pruning, "Tyro" says at p. 5, "We deprive the tree of its digestive organs without at all diminishing the absorption at the roots; the juices consequently not meeting with a proper surface of exposure, which if no summer-pruning had been performed they would have done, are returned to the tree in a crude and unprepared state, the wood thereby is not of a natural texture, and the fruit is deprived of its proper flavour." Many, however, do not so much deserve blame for pruning as for not pruning. The wall-trees in many places grow as they may, and rows of fruit-trees in the quarters of the garden are never pruned during the summer; all are generally left for the winter-pruning. The luxuriant growth of wood in summer robs the fruit of nourishment, and increases the extension of roots to supply the increased extent of branches on the following season. During winter, the knife removes a great portion of the branches, and the equilibrium that Nature has established between them and the roots is partly destroyed, and a luxuriance of fruitless branches continues to be produced on account of the increased powers of the roots. "In summer pruning," it is said, "we deprive the tree of its digestive organs without at all diminishing the absorption at the roots." I imagine that summer-pruning does diminish the absorption at the roots, and that it establishes a uniformity of circulation between roots and branches. There is such a mutual action existing between these, that whatever is done to curtail the one will affect the other; a judicious summer-pruning of crowded and luxuriant young shoots will allow a free circulation of air, and the genial influence of the sun will better mature the wood that remains, it will also moderate the action of the roots, and the reciprocity between them and branches will thereby be better established without the necessity of pruning much in winter. The use of a strong pair of scissors is all that is necessary for pruning fruit-trees in summer, when the wood is soft. By this practice, the juices supplied from the roots and the gases received from the atmosphere will be concentrated in the branches, and better fruit be obtained.—*W. P. Bamboo.*—Another

correspondent writes as follows: "If pruning commenced with the growing-season, and was uniformly carried on, the result would be very different from what arises from the bad practice of allowing a tree at midsummer to present the appearance of an unclipped hedge. The tree might well make a rapid and simultaneous outbreak from all parts; and even, as "Tyro" suggests, if the superfluous wood was left on the tree until the winter pruning, the rapid outbreak in spring, although not to such an extent as it had been in summer, will yet be much greater than is consistent with the permanent well-being or fruitfulness of the tree; for as sure as those strong growths are cut away after having become strong, so sure will the tree make vigorous efforts to replace them, unless the supply from the roots is interrupted. Hence the great good of root-pruning; or, what is perhaps better with young trees during the first three or four years after planting out, when they are so very apt to make strong wood, to lift them and replant them. If pruning begins as soon as shoots appear where they are not wanted, a great deal of wall may be gone over in a short time. The trees by this method will present a neat and healthy appearance; and the young wood, by being freely exposed to the action of sun and air, will be well ripened. Respecting leaves, when they are produced in great quantity they are generally small, and small leaves are by no means so efficient as larger ones are. Take the Vine for example: if the foliage is good, and has been properly exposed to the influence of light, &c., the wood will be strong, the eyes plump, and, under favourable circumstances, a good crop will be produced. Now the reason of all this is very obvious—it is breadth and health of foliage, and not numerical quantity that is requisite to elaborate the juices of a plant; two or three large and healthy leaves are better than a dozen small ones. Physiologists are in error when they forbid us to prune a forest-tree because a few of its leaves would be lost. This remark is equally applicable to fruit-trees; but still I am no advocate for putting the axe and saw mode into general use. Pruning, to be efficacious, whether on fruit or forest-trees, should be performed as soon as the part to be pruned is capable of removal.—*A. Dawson.*

Summer-pruning Fruit-trees.—One or two correspondents in a late *Chronicle* have started the question—how far is summer-pruning desirable? and they appear to say not at all. This is a subject deserving far more attention than it has hitherto received from gardeners generally; and so far as I can judge from my own observations, the summer-pruning of fruit-trees is productive of nothing but leaves to the trees and disappointment to their owners. I have pruned at all times, and, as far as I could understand them, exactly in the way directed by my authorities (books on Horticulture), but I can safely say that I never yet saw a blossom-bud upon the spur left for its production, if the tree was at the same time growing vigorously. It is true that by root-pruning or ringing the bark, I have made these spurs form blossom-buds, but these practices are not always desirable. I fancy, however, that I learnt a good deal on the subject from an itinerant Scotch gardener whom I employed to train and prune my trees some winters ago: his maxims were, "never cut away a twig in the summer that you can, by any possibility, get to the wall; for," says he, "did ye ever see a clipped thorn hedge full o' May-blossom? ye pit the trees quite oot o' temper when ye keep cut, cut, at them a' thro' the summer, an' it's just a battle between ye, whether ye tire o' cutting or they tire o' growing first: his other maxims were—prune freely in the winter; keep your tree well balanced; nail in, at full length, all young shoots intended for bearing; keep up a succession of young shoots to supply the places of those that are worn out and exhausted by bearing, and thin your trees when the growth of them is too luxuriant. I must admit that his fondness for ringing was carried to excess I considered a great excess, for he would ring Plums, Cherries, and Peaches, (despite of the gum), with as little forbearance as he would an old Crab-tree; however, he made the trees produce such crops as had not previously been seen in the neighbourhood. I trust some of your scientific contributors will offer a few remarks on this subject.—*T. G.*

Pruning Forest Trees.—This is a subject in which I am much interested, having inherited an extensive range of plantation and planted many acres myself. Dr. Thackeray states that he commenced on the removal of the trees from the nursery, by cutting two, three, or four branches from his trees, and from some, annually close to the stem, beginning at the top of the plant and descending, balancing the tree as well as he could. He further adds that his woodman and his assistants have persevered in this system at all seasons of the year removing all large important branches from the same tree once or oftener; the result has been that his trees have acquired strength and vigour, as is evident from the healthy appearance of them, as well as their augmented size. If this is the mode in which Dr. T. proceeds, I differ from him very widely. Should I be able to form an Arboricultural Society, Dr. T.'s plantations shall be visited. I hope to do this myself next summer; for my present purpose I will bring to my aid the positive knowledge we possess on this subject; and what could I do more as member of any society than to propose that theoretical disputed points should be referred? Mr. Billington, who had the management of one of the Royal forests in the north of England, now residing near Coventry, has given in a publication some valuable facts, the result of his experiments with Larches; one with the branches entire had increased 2¼ ins. in girth in each year for four years on an average; a second, with branches shortened, 2¼ ins., and another, with branches cut close to the stem, *only* 1¼ *ins.* Again, in another, his 2d division, a tree with branches cut close in four years, had increased 4 ins.; the tree with the branches cut increased 7½ ins. in four years, making one inch in each year more *than the other*, an object well worth attending to. These facts are superior to theory. What, then, is the value of Dr. T.'s universal pruning at all times of the year? Great improvements have taken place in Agriculture in sowing Wheat in drills a good distance apart, saving one-half of the seed, and producing a larger crop. I hope, therefore, that gentlemen will know the great advantage of only allowing a certain number of trees to grow on the ground; as many only as it will support and bring to maturity. An incalculable loss takes place in England by the mismanagement of woodland property. Cut wood and have wood is my motto, after 30 years' experience. I cut away trees where there are too many. I wish to shape my practice in accordance with the laws of nature, and not to set myself in opposition. I expect to find her a kind handmaid if I woo her skilfully, but a very termagant if I resist her. "Quercus" has been attacked, because he has advocated nature, and is advised by one gentleman from the county of Kerry to take a journey to Chester, to ascertain by his own inspection the state of the Nerquis plantations. If Dr. T. would have the goodness to say what is the height of his trees, and at what distance they stand from each other, "Quercus" would then be able to form a better judgment. It often happens that by pruning severely the owner thinks he can keep so many more trees on the ground. Thus, one giant evil produces another, and both end in complete ruin.—*James Hamerton, Hellifield Peel.*

Hammond's Cape Broccoli.—I suspect "W. N." must have received some other kind of Broccoli than Hammond's Cape. With us, at Broadlands, no signs of tenderness are visible, even during sharp frosts; the heads are large, and as close and white as a Cauliflower. It continued in use until a fortnight ago, and if enough had been planted it might have been prolonged until February.—*Samuel Hinman.*

The Fig.—Many papers have appeared from time to time upon the culture, pruning, and management of this plant, but we are still as much in the dark respecting it as we were 30 years ago. It still remains independent of man's control—producing abundantly, or continuing barren, year after year, as though it were the sport of chance, or were governed by influences wholly unknown to science. It seems that there is but one object to be accomplished towards bringing this wayward producer under subjection: it is admitted by all that the only crop of fruit which can be expected to ripen in the open air in England is that which is produced upon the Midsummer shoot of the previous season, upon which the fruit-buds are formed which, if not sufficiently advanced to form the second crop—to fall unripened with the first frost—become the fruit of the following spring. If, therefore, some means could be devised by which, as soon as the Midsummer buds are formed, the further growth of the tree could be checked, it seems reasonable to suppose that we should be able to insure a crop in the next season. Possibly, you may be aware of some experiments having been made with this object. Would taking the tree up, or pruning the roots in autumn, have this effect—or could you suggest any other means by which this object might be attained?—*J. J.* [We are happy to say that one of our correspondents, a first-rate practical man, is preparing a paper on this subject.]

To Destroy the Wireworm.—When I get in my turfy loam, I have a copper of boiling water ready, and as the turf is stacked up, upon every layer of it I pour from the rose of a large watering-pot (holding it down quite close) a good drenching of boiling water; I then add another layer of turf, and so on throughout the whole. It effectually destroys insects of every kind, and materially assists the decomposition of the turf. If the loam remains for a length of time before it is used, when about to pot Carnations, or any flower suffering in an equal degree from the attacks of wireworm, I spread upon some hard ground the compost I have prepared for the purpose, and giving it a good sprinkling of boiling water, I allow it to remain until it is dry.—*Rusticus.*

The Himalayan Funnel.—It has frequently been your business, no less than your pleasure, to discuss the various forms and materials of garden-pots and watering-pots, which, as appurtenances, however humble, to Horticultural pursuits, you seem to have thought invested with as much dignity, derived from usefulness, as entitled them to your attention. On the same principle you will perhaps be disposed to notice a prospectus which I send you, announcing a new chimney-pot, which, as flues and fires are essentially Horticultural, has a fair claim on your consideration. This particular chimney-pot has, however, a double interest; it is no vulgar invention of some subannuated sweep, driven by the relentless humanity of Parliament to seek, as *Punch* has it, consolation in distant *climes*; but it has been imported from the Himalayan Mountains, 28,000 (?) feet above the level of the sea, by an enterprising British officer, who, whatever he may think of fire, is clearly not afraid of smoke. I would be serious on this subject for its own sake as well as its associations. Who, indeed, can contemplate a Himalayan chimney-pot without thinking of a Suttee, or muse upon the circumstances which have carried the mechanic arts to such a height in those benighted regions, without imagining some mysterious connexion between the Brahma of their idolatry and the Bramah of ours? A new Himalayan plant with some unpronounceable name would have been an object of interest; but a Himalayan chimney-pot, the produce of Himalayan intellect, in an opposite to the former as mind is superior to matter. Whether, however, how this may be, the chimney-pot in question is based upon the most recondite principles of science—mechanic, pneumatic, hydraulic, &c. (some great call it so—indeed, it is, and, by no means, least, that it is adapted to a new acquaintance of the Sultan, either suffocated by the fumes of the 68th, 6 and 7 Vic. The happy possessor of this immaculate chimney-pot may bid defiance to the winds; for while, as the proprietor states, with infinite candour, "most other inventions are singularly adapted to increase the evils they profess to remedy," this can never fail. Let the storm blow up or down, or right a-head or round a corner, north or south, or east or west, this universal apparatus turns the blast to its own account, and compels it to aid in the escape of the smoke. Tempests cannot shake it, nor floods overwhelm, nor fire consume it; and it is made of such enduring materials, and in such diversity of shapes, that age cannot wither it, nor *custom* stale its infinite variety. I could say more on this topic, were I not fearful of subjecting you to a claim for the advertisement duty, which it is your duty not to evade; but I have thought it my duty, nevertheless, to prepare your readers for the forthcoming announcement of the Himalayan Chimney-Pot.—*Fumus.*

Budding and Inarching the Vine.—Wishing to increase the number of Muscats of Alexandria and Cannon Hall Grapes, I cut down a few Vines; one-half of them was budded, and the other was inarched. To test the merit of each method fairly, both budding and inarching were done at one period. The result is, that by the former method, bearing wood has been produced nearly double the strength of that by the latter. In budding, the following is the method I pursued:—The old Vines were cut down in the autumn of 1842. They were laid in March, 1843; as soon as they had made shoots a few inches long, two were selected on each Vine, and all the others were taken off. These were tied in, and laterals were pinched regularly off them until May. The young shoots were then about two-thirds up the rafters, and nearly full-grown in thickness at the base, but not ripened or turned brown. At that period the buds taken from young shoots with leaves not larger than two inches in diameter, were put on; the wood was left in the buds; they were inserted in the usual way, and tied firmly with a piece of matting. In the course of ten days or a fortnight they were united, the matting was undone, and the shoots were cut down to the buds; all shoots below the buds were taken off as they made their appearance. After this was done they grew away very strong and rapidly. Some of the buds showed fruit, but this was pinched off. The leaves attached to the buds never flagged.—*W. G.*

The Heckfield Pit.—Some inquiry having been made as to the manner in which this pit (of which an account is given at p. 892 for 1843) is managed, Mr. Berry has been so obliging as to forward us the following statement:—Respecting the mode of getting over the difficulty of the plants subsiding too far from the glass, we endeavour to prevent this evil by filling the pit pretty full, with the stuff put compactly together. The ridge of mould is laid along the back, and the plants are planted along the ridge, within 18 inches of the back wall; they are trained towards the front, sometimes on a trellis, and sometimes without. The plants being placed near the back, the roots are more secure against injury from over heat, whilst ample space of surface is left in front for stirring up, &c.; and, if it is requisite, a few inches of dung are added to the surface before the bed is finally earthed over. The trellis, or rather a small trellis under each light, is formed with two pieces of wood laid across the bed, having notches cut out on the upper edges for the reception of pieces of lath, which are laid in as they are needed; this trellis is supported on four short stakes stuck into the bed. But it may be asked whether a breakage of roots does not take place on the edge of the back flue as the bed subsides? this would certainly take place, but is prevented by a few slates set along the edge of the flue to keep the dung and earth off it. This caution, however, is only required in one of the divisions of our pits, because the cavity in its flue is 5 inches, whilst the cavities in the others are only 2 inches, and that part of the flue on which the dung would rest is sloped off, so as to offer no obstruction. I may observe, that the back lining is the one on which most dependence is placed in keeping up the heat.—*Thos. Berry.*——Another correspondent, Mr. James Selsby, proceeds somewhat differently:—To prevent the Melons from leaving the glass as the litter sinks, I make a false bottom eighteen inches from the glass, consisting of joists let into the front and back wall. The joists are about twelve inches asunder, and upon them are laid hurdles, or if these are not at hand, sticks fit for hurdles placed about two inches apart will answer the purpose; and upon the hurdles, or sticks, must be laid thin turf, such as is cut for lawns, the grass side to be downwards, and the pieces placed close together, so as to keep down the steam which rises into the hollow space from below, and gets through the pinsome holes from the linings. I find this plan answers better than a solid bed.—*James Selsby.*

Foreign Correspondence.

Paris, Dec. 27, 1843.—The observations in my last letter referred exclusively to the cultivation of Vines in the Kitchen Garden of Versailles, but I said nothing about the seedlings, of which there are a great number now coming into fruit. It would be difficult to determine, from the habit of the plants, from what kinds they were obtained. I understand, however, that the whole are from the Bauville, without artificial impregnation; if so, it is a sporting variety, for the greater part are very unlike the parent. Some have compact bunches like Chasselas, others large bunches like the Frankenthal, some like the Bauville form; some like Chasselas, others like Austria's Queen; some the Bauville, with white stalks like Chasselas, and some very large bunches, with smooth leaves,

[illegible] fruits upon the stems [illegible] the [illegible] Pine-apple, but much brighter in colour, and [illegible] above it the earth. Many seedlings have before been raised in these gardens, but none which the [illegible] sufficiently distinct and good to name. I may mention, *en passant*, that the Banana Plants presents, just now, an interesting appearance; it is about 25 feet by 12; if it were planted last year, in the open ground, four suckers, all of which are now in fruit. On one of these I counted nearly 150 pods, which, when ripe, cannot weigh less than 30 or 40 lbs.; the plants have about 2 feet of soil, upon a 3 feet bed of leaves. It is hardly necessary to refer to all the Pineries that I have visited; suffice it to say, the same remarks will apply generally to Meudon and Saponnay, as well as to the growers for the market. In each of these places you find the open-frame culture, not only for young plants, but continued in the after stages, especially for the large kinds.

I have before said that Peat is the principal soil in use, indeed, so general is this, that among the many public and private establishments which I have visited in France, I have never yet seen loam used in any one of them. In one or two you may see a few growing in sandy earth and rotten leaf-mould, and here and there peat and leaf-mould, but pure peat is everywhere to be seen as the favourite soil; this may seem strange to English growers, who have so long been accustomed to such strong soils as the Norwood loam, but, nevertheless, the fact is as I have stated. French growers will not use loam, some have told me that it has been tried upon Camellias and Roses, and that they have died under it, I even know an English gardener living with a lady of title, near Paris, who has adopted the same views, and replanted his Camellias in peat, after a trial of three seasons in loam. I have endeavoured to convince them that their want of success must have arisen from an improper use of loam in a sour state, but all to no purpose, their *amour propre* is as easily wounded in Horticulture as in Politics. They ask, are your Pines more healthy, or your fruit larger, than ours? and without waiting for a reply, tell you that they have seen Mr Wilmot's, Chatsworth, and other gardens in England and Scotland, and are satisfied that their plan is the best, this may be prejudice—perhaps it is so, but I apprehend that both Mr. Glendinning and Mr. Spencer would find some difficulty in combatting such evidences as 10 lb. Pines, which the French growers could produce in its favour.

The establishment of Versailles is, as I have before said, the largest in France, but that of Meudon is also remarkable for excellent culture and the high state of perfection to which this fruit is brought. This is one of the King's private establishments; the Chateau is never occupied by the Royal family, and M. Pelvillain, the chief gardener, is allowed the kitchen garden on his own account. The Pine is his hobby, and he spares no trouble or expense in bringing it to perfection; so ardent is his desire to obtain information, that he is learning the English language for the express purpose of reading our treatises and visiting our country, that he may be able to judge for himself of the advantages or defects of the different modes of treatment. He uses Peat, and also adopts the open ground culture, and certainly it would be difficult to find plants more vigorous, or finer fruit at Christmas, than he produces, it is no unusual thing to see in his houses Providence, Cayenne, and Enviles from 8 to 10 lbs. The Queens, however, are not large, certainly not more than 2 or 3 lbs. on the average, these last he grows principally in pots for the market, the confectioners of Paris seldom buy the larger kinds, they prefer a middle sized Queen to any other; it would, therefore, be useless for him to take any extraordinary trouble in getting this variety very large. He has also raised several seedlings within the last four years, one of them was sent out about two seasons since, it is not, however, considered any great improvement upon the original. I know that many English amateurs and gardeners have from time to time visited Meudon, and they can bear testimony for or against the justice of my remarks.

MM. Goutier of Paris and Truelfaut of Versailles cultivate entirely for market, the former grows almost every variety, but I do not think his fruit so fine as at the before-mentioned places, this, however, may be on account of the little demand for heavy fruits. I have, nevertheless, seen excellent specimens in his houses. Pines are not sold in Paris by weight, and therefore he has no particular inducement to obtain them above the usual size. He has likewise raised a great number of seedlings from the Enville, which bear a striking resemblance to those obtained at Versailles; the same diversity in habit and fruit is apparent, and it is somewhat singular that as many, in both places, should have smooth leaves, because, at the time the seed was perfected, the Cayenne Lis was but little cultivated. At the last Paris show in September, M. Goutier obtained the large silver medal for two of his seedlings, and you will find a description of the fruit in my letter of that period; among other of his seedlings I noticed one having a long Enville-shaped fruit, of a greenish orange colour, weighing about 5 lbs.; another named Prince de Joinville, having large and long fruit of about 7 or 8 lbs.; another with smooth leaves and very long angular fruit, about 12 inches long, weighing, I think, 7 or 8 lbs.; another named Enville Pelvillain, with very large fruit, said to be of a finer flavour than the old variety; there were five or six others with large fruit, all varying more or less in habit or fruit from the parent. Mr. Beaumont limits about 400 Pines annually; all of which, either the production of a few Cayennes and Providences, and Queens; about 100 are planted in the open ground, both are not particularly very marked difference between them and the Queens in pots; the fruit, he says there would be no particular advantage to him in producing large fruit; he finds a ready sale for ordinary sized Queens at 10 and 12 francs, while the larger kinds are seldom asked for. He, however, is decidedly in favour of open frame culture for all varieties of young plants, and for the fruiting of the varieties before mentioned. Such is the result of my observations, and I think it will be conceded by all that French cultivators are entitled to no little credit for the introduction of this system; it is a common saying in this country, "that the French invent, but the English practise and reap the benefit." I doubt not it will so be in this instance, for I feel satisfied that, *malgré* the climate, there will be larger fruit produced under this plan by Messrs. Barnes, Spencer, and others, than has ever been seen here. Not only can England boast of the most skilful practical gardeners, but she enjoys peculiar advantages from the great perfection to which her heating by hot water is now brought, and should Rendle's tank system be found as favourable as he supposes, I shall not be surprised to read before long of prizes being awarded for Pines weighing 12 or 15 lbs. each.

Societies.

MICROSCOPICAL SOCIETY.

Jan. 10.—J H Bowerbank, Esq, in the chair. There being no paper Mr John Quekett, the Secretary, made some observations on the structure of a fossil human bone found in a bog. He stated that many attempts had been made to inject artificially the Haversian canals of bone, but had failed, but in this instance the medullary canal, the Haversian canals, and the osseous corpuscles were beautifully injected. Dr. Goodfellow stated that he had seen preparations of Mr Tooms, in which he had succeeded in injecting artificially the Haversian canals and osseous corpuscles. Mr. Dalrymple said, with regard to the structure of the Haversian canals, he had not only seen vessels running through them, but vessels lining their walls. Mr John Quekett also made some observations on the analogy between the structure of the air bladder of the eel and the lower part of the lung of the Chameleon thus proving the respiratory function of the air-bladder as well as its structural analogy with the lungs. These remarks were illustrated by microscopical specimens.

Reviews.

An Introduction to Practical Organic Chemistry. 12mo. Pickering.

Why this should have been called an introduction to *practical* chemistry we are at a loss to understand for it is anything rather than that. It is, *in fact*, an exposition, in few words, of what the author conceives to be the modern *theory* of organic chemistry, taken from the writings of the more conspicuous of modern investigators. In some respects the author has performed his task with skill, and has made it a real assistance to those who are labouring to infuse some idea of the nature of chemical investigation into the rising generation. In other respects he has been less successful. For example, the questionable, if not fallacious doctrine of root-secretions is now, in 1844, treated as if it were a matter beyond all doubt, and the ten times refuted speculations of geologists as to the presence of enormous Ferns in the beds of coal are regarded as so many facts about which no doubt can be entertained. In another place we are assured that pruning fruit trees make them bear more abundantly, which we believe is the reverse of the fact. Pruning does not produce abundance, but it improves quality.

What we most approve of is the skill shown in demonstrating the truth of the Mosaic history of the creation by the evidence of modern science. "Let us consider," says the author, "the apparent course of creation as these sciences—chemistry and geology—present it. From the seething matter of volcanoes, carbonic acid, combinations of ammonia in a gaseous form, chiefly carbonate of ammonia, and aqueous vapour are evolved, i. e., gases composed respectively of carbon and oxygen and hydrogen and nitrogen, or a combination of both, but none of them capable of maintaining animal life; and steam, which is a compound of oxygen and hydrogen. Plants sprout from the earth, and find nourishment for the most luxurious growth in the gaseous products of the heated mass. The remains of enormous Ferns found among deep beds of coal, showing the latter to be the produce of a former vegetation, prove how immense a portion of vegetable matter was produced from gases which no animal could have breathed. The absorption of carbonic acid, with the consequent return of a large quantity of pure oxygen to the atmosphere; the greater affinity of hydrogen for the oxygen thus presented than for nitrogen, especially when heat acted in the decomposition of ammonia, which would then set free its portion of nitrogen—brought the atmosphere apparently in the course of time to its present composition; and animals then stepped forth upon the earth, to breathe the air, and consume the food already prepared for them. Such is the account which science would give, it differs in nothing from that of Moses."

To our minds nothing can be more satisfactory than this, with the exception of the romance about Ferns, and we accept it as a sufficient atonement for errors on other points.

Miscellaneous.

Mode of ascertaining the Quality of Seeds.—Such seeds as do not naturally require a very long time to germinate, are sometimes readily examined, as regards their goodness, by being placed in hot dung. The following particulars of the mode indicated by General Yconat is recorded in the "Revue Horticole." A pinch of seed is sown in a path, which is plunged in fermenting horse-dung, the seed being covered with nearly half an inch of soil, and over this rather more than an inch of dung.‖

Swan River Vegetation.—Labiatæ, &c.—We have several fine species of Hemiandra, Hemigenia, and Anisandra. There is also a species of Westringia, a Menthoid, nearly allied to Pennyroyal, and several showy plants with a calyx like Scutellaria.—*Drummond, in the Inquirer.*

JANUARY

By the Author of "Rural Sonnets," "Spartacus," "Eugenia," and other Tragedies.

Happy as yon fresh Bays upon his brow,
With full-blown Laurustinus interwov'd;
Ere yet the husbandmen resume the plough,
Or festive days by labour are retriev'd—
Lo! *January* leads the young New Year,
Happy in welcome, and with hope elate,
Tho' round its form cold winds and clouds career,
And barren would appear its first estate.
Now—if the weather freeze, or bind the ground—
Manures are carted and the routes repair'd
In forest-haunts the woodmen's strokes resound
For earliest produce gardens are prepar'd
And here and there just peep above the soil
Signs of the life whereon'th vast Nature a womb doth toil.

T. Jan 2, Inner Temple, Jan 20, 1844.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

This is a good time to remove dormant bulbs and tubers to a forcing pit, such as the many varieties of *Hippeastrum*. If these have been put to rest in their pots it is best not to disturb their roots at present; if they want larger pots shift them when they are in full growth next month. Some of the different Gloxinias and a few of the Achimenes may also be set to growing; these do best potted at the time they are started. Some of the Gloxinias are apt to damp off, if water lodges in the crown of their tubers. Seeds of stove plants or from foreign parts may now be sown in well drained pots in peat and sand, the soil for valuable seeds ought to be prepared after Mr. River's manner, if only to kill eggs of insects seeds of weeds, and to expel dampness. Look over all plants regularly, and let everything be clean about them.

Conservatory.—Where forced flowers are introduced less air should be admitted than for a collection of greenhouse plants. See particularly that Orange trees Nerliums, and other plants are clear of mist before they begin growing, as young wood and foliage are very difficult to clean without injury. Most succulent growing plants being in full growth and bloom, require less water than these in smaller pots in the greenhouse. Rhododendrons and Azaleas are among the finest and easiest plants to force for the conservatory and seeds from forced plants of them grown are always more to be depended on for novelties than those from the open ground.

Greenhouse.—Seeds of Heaths, and of all woody half-hardy plants may now be sown and reared in hot beds or stoves; but it is soon as to sow them where such conveniences are wanting. This is also about the best time to sow Rhododendron and Azalea seed, especially the finer sorts; seedlings of these of last year might now be forced, and afterwards hardened off against next May when they might be planted out in cold frames or sheltered beds. This treatment brings them sooner to a flowering state, they also make finer plants. Keep greenhouse plants from growing yet as much as possible.

Forcing Pits.—Many other plants besides those for flowering might be brought on early growth in these pits. The Paulownia should now be set to growing as a forcing plant; as soon as the blooms are ready to expand the plants should be removed from close heat to a more airy situation for a day or two before they are brought to the conservatory or sitting rooms; syringe them at least once a day, keep the plants free from insects, and introduce as many plants as you can spare for experiment. There are many plants probably that will force well which have not yet been tried.—*D. D.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out door Department.

Never had we such a fine season for out door improvements or alterations; but tender plants are in a very forward state, and it is necessary to keep them securely protected at night, as frost may come upon us when we little expect it. Many plants, such as the Tree Pæony, Magnolia conspicua, and some of the more hardy of the Himalayan Pinuses, are in a very forward state and will require watching, or we may lose a season's growth.

Reserve Garden.—A part of this garden should, in all large establishments be devoted to the rearing of evergreen shrubs, such as Laurel, Rhododendrons, Kalmias, Yews, Laurustinus, &c., which may be propagated at home or bought in from the nurseryman when a year or two old at a very trifling cost. They come in very handy when making improvements, and ensure to grow from being habited to the soil and climate of the place. There are not many places where a few thousands of these might not be planted with great improvement to the grounds.

Pits and Frames.—Protect securely at night, but give all the air possible in the day time. Calceolarias, Heliotropiums, &c., may be potted off preparatory to being hardened for the flower-garden. Should the weather send the men in doors, a few barrow loads of pegs may be cut, of various sizes, ready for pegging down shrubs, Roses, Verbenas, &c. &c. Masons may also be made of various sizes and flower sticks painted, straightened, tied into bundles and laid up to dry.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas may now be top dressed, removing carefully the surface soil, and substituting some two year decayed horse manure and loam soil. Avoid all hot stimulating composts, for though they may increase the size of the flowers for the present season, yet it is "*a food*" so uncongenial with the nature of the plant that the foundation of future disease will be most assuredly laid.

Polyanthuses grown in pots to be kept moderately dry, and a similar top dressing as to the *Auriculas* recommended for the *Auriculas* will be of infinite service to them. They are, however, grown on beds, with a north east aspect with great success. A cool bottom, either natural or artificial is what must be borne in mind, as a *sine qua non* for the perfection of the flower.

Carnations.—Still give all the air possible. If the green-fly begins to be troublesome remove it with a camel-hair brush.

Pinks.—As spring advances the wireworm gets more active and mischievous. If you have reason to suspect that any of these work in your beds cut a P take into quarters inserting a shower of coal place them in various parts just below the soil, and examine them daily. This is an effectual trap.

Tulips.—We have as yet had but little frost or wet to affect the crop. As they advance they will require strict attention to the precautions before directed.

Ranunculuses.—In selecting roots for blooming choose those with a high crown in preference to size. The following are a few that will make an improvement on any collection.—Tyson's Edgar yellow, edged with puce; C star's Apollo crimson self; Mr Welch white, edged with deep pink; Madeline, white, a beautiful rose edge; Bartlett's Charlotte, superbly mottled; and Luther, white, purple edge. The old flowers—Hazara, splendid dark; Socrates, silver; and Le Temeraire pink stripe—still continue the best in their respective classes, most of the new seedlings being clumsy-edged, spotted, or mottled.

Pansies are showing a tendency to bloom, arising from the

plant mild weather. They will be better protected as they are.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—If in looking over the succession plants any are observed to be unsightly, the sooner they are discarded and repotted the better, choosing a mild day for the operations. They will soon begin to make new roots in the fresh soil, and will be re-established before the dark days have much power. Those plants that are in good condition at the present, and not likely to require the soil to be shaken from them, but merely shifted into larger pots, will do better if this is delayed until the beginning of March.

Vinery.—If there is ample means of obtaining a moist atmosphere, it will be necessary to pay some attention to this point during damp close weather; as it is possible to have more than is necessary for the health of the Vine after it is in leaf. Keep watch sticks in the fermenting material upon the borders and examine them frequently to see if the heat is regular; so of heat will be a good medium.

Peach House.—A small portion of air admitted throughout the day, during the blooming of the trees, will prove beneficial. The blooms will be stronger and of a finer colour, and the fruit will set better. Peach trees generally set their fruit best in houses not continuously glazed, and this affords us a lesson.

Fig-House.—As the young Figs begin to swell increase the temperature 5° or 8° in a week, till it reach 60° or 65°, with a rise of 5° to 10° by day, according as there may be sunshine or not.

Cherry House.—From the time the bloom begins to expand do not syringe till the fruit is set; keep a steady heat of 55° by night and 60° by day. Ventilate as directed for the Peach-house.

Strawberries.—See last week's Calendar.

Melons.—Prepare now a bed of well-fermented dung and leaves for planting out soon, using faggots of brush-wood for the first 2 feet in height.—*J. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Trenching.—Prepare the ground for those fruit trees the planting of which could not be effected in the autumn, by thoroughly draining the borders and forming a substratum through which the roots will not easily penetrate. In the absence of paving-stone, tiles, &c., a good substitute may be formed of coarse gravel and finely-sifted quicklime, in the proportion of one of the former to one of the latter, mixed well together with a sufficiency of water, and laid down to the depth of four or five inches. From 15 to 18 inches depth of soil will be sufficient for Peaches and Apricots, much less will do, if the borders are hollowed and cropping dispensed with. No manure ought to be mixed with the soil.

Cucumbers.—Prepare fermenting materials for their growth in frames. Those who wish to have them early will have commenced long ago.

Routine Management.—Dig, ridge, and turn up all empty ground in this favourable weather. Give plenty of air to all advancing crops in frames. Clean and stir the soil among all growing crops in the open garden; remove all decaying leaves, keep the walks and borders in good order, and render the kitchen garden not merely an object of necessity, but of *sight* and interest.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Proceed with the works previously pointed out—such as felling trees not wanted for the bark, planting fresh ones where required, relieving others from the overgrowth of adjoining trees of less value, and training any young promising plants by taking off or shortening any side-branches at some distance from the stem, that are not over large, so as to cause a wound that would not soon heal over. When a young thriving tree is near to one that should be cut down in a few years, much good would result if some of the branches of the tree intended to be removed were shortened in a little, to make room for the branches of the young one.

Coppice.—Such stuff as is not likely to be saleable, namely Hawthorns, Briars, Brambles, Honeysuckles, and things that spring up and injure good wood, should be kept under. Proprietors of woods are not aware of the loss they suffer by not attending to this.

Young Plantations.—In addition to what I advised last week, when thinning and training young plantations, a person with a light ladder and a narrow hand saw, about a foot or 14 inches long, would be beneficially employed by taking close off some or all of the very strongest side-branches. Many that would have been fine trees are entirely ruined by neglecting this until it is too late. This operation would prevent all future suppose of trees.

Hedge Rows.—The same care and attention to dressing hedges previously mentioned should be attended to as respects maiden plants. Continue to plant others where necessary, if you have suitable well-prepared stocky plants. When planting trees in hedge-rows exposed to strong winds give them a little inclination towards that point, and put a firm soil on the opposite side close to the stem.

Nursery Stock.—Proceed with all necessary work in taking up trees for replanting, preparing ground for seeds and plants, and begin planting seedlings and cuttings of larger plants in rows in the ground.—*R. R.*

VII.—COTTAGERS' GARDENS.

As the weather still continues favourable, the cottager, if it is not already done, should proceed with trimming and cleaning out any hedges that are under his care, before the season commences, when other things will occupy all his spare time. An evergreen should always be a leading feature in a cottager's garden, everything that can be done to promote this should be forwarded now, when little else can be performed. Anything that decays unsightly, and that will make manure, should be removed to the rot heap, which should be turned over occasionally and covered with a little soil; this prevents all noxious effluvia from escaping. The soil also mixes among the decaying vegetables, and becomes excellent compost. Soap-suds have a good effect on many kinds of vegetables, and should not be thrown away; they are beneficial on soils where Cabbages are infested with the club, and in some instances have been known to entirely cure that disease.

Vegetables.—A sowing of Radishes may be made on a warm border, but they must be protected from frost by covering the soil with straw. If any digging or trenching yet remains to be done no time should be lost in getting it forwarded while the weather will permit.

Fruit.—In pruning Gooseberry and Currant-bushes care must be taken to thin them well out in the centre, so as to admit plenty of sun and air. The same remark is also applicable to standard Apple trees; the middle of the tree must be kept quite open, taking care that all the branches lead outwards, and preserving a regular distance from each other. Pear trees should also be thinned well out, and the produce will be much better in quality.

Flowers.—Pelargoniums, Fuchsias, &c., in pots, should have as much light and air as possible; they should be sparingly watered, and this ought always to be done in the morning. If they are inclined to grow up tall and slender the points of the shoots may be pinched off by the finger and thumb, and this will induce them to throw out side branches, and make them dwarf and bushy. Anything that is likely to be injured by frost should be carefully watched and protected from it by straw or [illegible].—*Mr. H.*

A Statement of the Weather at Greenwich during the last 12 months, for the corresponding Week ending February 3, 1844.

Jan.	Aver. Minimum Temp.	Aver. Amount Temp.	Mean Temp.	No. of Years in which it Rained	Greatest quantity of Rain	Prevailing Winds
Sun 28	44.1	50.6	47.3	8	0.17 in.	W.
Mon 29	44.0	52.6	48.3	5	0.42	W.
Tues 30	43.0	52.0	47.5	4	0.12	W.
Wed 31	42.6	52.2	47.4	9	0.24	W.
Feb.						
Thurs 1	42.4	53.1	47.8	6	0.39	W.
Fri 2	42.9	52.4	47.1	5	0.75	W.
Sat 3	44.1	52.9	48.6	9	0.62	W.

The highest temperature during the above period occurred on the 30th, 1843—thermometer 58°; and the lowest on the 30th 1839—thermometer 17.

Notices to Correspondents.

MR. PAXTON'S COTTAGER'S CALENDAR.—At the earnest solicitation of many of our Subscribers, we have determined on again reprinting Mr Paxton's "Cottager's Calendar," in the form of a small volume, for general distribution, price 3*d* each copy. It may be ordered of all booksellers. Gentlemen wishing to *distribute copies* among their cottage tenantry, may have them *delivered in any part of London*, by remitting a post-office order to this office, at the rate of 5*s* for every 25 copies.

OUR CORRESPONDENTS will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

COMMUNICATIONS from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them:—*Martin Doyle, O., W Billington, J W A., Vita, J Brighton, A Friend to Horticulture, O J L Snow, G Thompson, J Paxton, A Practical Man*, and *P. Mackenzie*.

ANEMONES.—*H B.*—The unusual mildness of the season, together with the close covering applied too early, have caused a premature growth in your roots. On discovering this disaster, the better treatment would have been to have removed the litter by degrees, in order to harden the tender shoots gradually. By their complete exposure, it is probable most of them will perish; a little time will show you whether it will not be better to sacrifice the bloom for this season, in order to strengthen the roots for another year. At present, you must cover the beds with litter at night, and in severe weather; give all the air possible when the weather permits and keep mats in readiness as an additional covering in case of frost.

BOOKS.—*H Y Denny.*—Mr Loudon's contributions to "Brande's Dictionary" cannot be purchased separately. His "suburban Horticulturist" never appeared.—*One* should procure "Parnell's Grasses of Scotland." We are not carpenters, and cannot answer the other question. He who expects to learn to cut wood by books will be very likely to cut his fingers.—*Pruning Knife.*—Mr Loudon's "suburban Horticulturist" probably contains the information you want. Some day, when we have not so many other things to do, we will give a series of articles on the subject. The first principles of pruning will be found in the "Theory of Horticulture," but, we confess, treated too concisely, even as a matter of theory.

CAMELLIAS.—*E R.*—Camellia alba plena and C. fimbriata alba are perhaps the most delicate varieties in cultivation. The reason they are so apt to drop their flower buds is owing to too many being left on the plant. It is not uncommon for some Camellias to produce twice as many flower buds as they have strength to expand, then the consequence is (if not picked off at an early period), they will drop off, and those that remain will very often be deformed or diminished in size. This may also be the reason why your C. eximia has not proved true to its character this season. If we wish good blooms we cannot have many on a plant. Wherefore Camellias' apart is uncertain. It is owing to the presence or absence of colouring matter secreted in the cells of which the petals are composed; but the agents upon which these phenomena depend are unknown. We not unfrequently see on C. Donckelaeri on the same twig one flower pure red and another blotched with white, without any apparent cause.

CHARCOAL.—*J A.*—Add to the soil of your Pelargoniums one quarter of charcoal in coarse pieces. We do not like the fine powder. We have, however, never seen this substance tried on Pelargoniums. If you want to make them grow very large strew the top of the soil with burnt bones, and moisten the bones with oil of vitriol just when they are beginning to grow.

COMMELINA COELESTIS.—*Flora.*—The roots of Commelina coelestis may be planted out into a tolerably rich bed about the middle of April, they may either be taken up in autumn or protected by covering the ground with ashes, leaf mould, or sand; but to take them up is the best way to insure their safety. Pavonia tigridia will succeed planted out in the open border in summer.

FRUIT TREES.—*Banffshire.*—The cheapest and only way of clearing your "Barrie bushes and Apple-trees" of lichen is thoroughly draining your land, which will produce other advantages besides. We do not know what the Corn grub is. The Gooseberry Caterpillar may certainly be killed by White Hellebore powder, *if sit is fresh*. The transformations of the latter are described at p. 518 of 1841.—*Morley.*—Peach, Nectarine, and Apricot trees, round which a trench was made and filled with rotten dung unmixed with soil, will be apt to gum in consequence.

GLOXINIAS.—*M T G.*—These cannot be raised in a greenhouse, as they require a temperature of about 60°, but by starting them about the beginning of March, and growing them in a hot-bed until they show signs of flowering you might perhaps be able to bloom them in a warm corner of a greenhouse during the summer months. While they are in the frame great care is required to keep them from damping off, they must not be overwatered, and air should be regularly given them when the weather will allow.

HEATING.—*Amateur No 1.*—Water will not shrink in gutters, but it wastes by evaporation and insensible leakage. If you don't want to use your pit in winter you may lay your slates on the gutters without bedding them in cement; but if it is to be used for winter purposes the slates must be bedded in either cement or mortar, or the pit will prove too damp.—*Amateur No. 2.*—We see no objection to such a boiler as you mention, but we are unacquainted with it. In consequence of your having mixed up other questions with this, we had overlooked the latter, and must defer answers till next week. Azaleas and Rhododendrons do not like dry banks, they prefer moist situations, they may, however, be made to grow by the use of abundance of cow-dung.—*Suffolk.*—We should say that a pit 3 or 4 sashes long would be the smallest to which any hot-water heating can be advantageously applied. However, if you can adapt an iron saucepan to the gutters in the little pit you wish to build, and don't mind some waste of fuel, you may perhaps get the heat you want without much trouble. Or if you can get an old flued manger with square sides it would be easier to fix the flow and return pipes to it. Or an iron chimney pipe, closed at the end in the fire, and standing upwards into your gutters will do, without any return-pipe at all. Ingenuity will vanquish many difficulties.

TRANSPLANT.—*R. H.*—The orchideous plants in your greenhouse Pleione, Calanthes, &c., are the finest we have seen. They were therefore just figured in the last part of our Botanical Magazine. If their treatment be given in the "Journal of the Royal Agricultural Society," any information regarding them will be very acceptable at this time to Mr. Curtis.—*A Subscriber.*—*C.* 1 is a Millipede, called *Julus terrestris* or an allied species. 2 is the wheat-worm.—the property of increase by division is certainly curious. 3 is the larva-case of a Noctua, but of what species it is impossible to determine without hatching the moth, and the pupa has been killed by pressure; 4, Cercaria (Silcus) lineata is one of the Weevil tribe; 5, pupa of some fly, like Musca domestica, and generated in the dung of animals, or amongst bones. The last animal alluded to by you may be a Leptinus, but without seeing specimens it is not in my power to speak with certainty.—*R.*—If *Lambton* will forward some of the infested seeds and insects to Mr. Curtis, his queries will be answered; but without these materials it is neither possible to investigate this important subject nor to form a correct opinion of the remedies.—*R.*

LILIUM LANCIFOLIUM ALBUM, &c.—*A. B. D.*—I have grown this in the open air for two years, and consider it quite hardy. Last season I had a bed containing about 150 flowering bulbs, which bloomed much better than the common kinds of Lilies; and had it not been for the unfavourable weather of last spring, they would have been excellent, but on this account were comparatively short, and some of the foliage and a few of the flowers were injured, but not so much so as the common Orange Lily. The bulbs lifted quite well both seasons, and did not lose a single root from frost.—*L. lancifolium punctatum* I have not tried in the open air, but no doubt both that and *rubrum* would do equally well. *L. auratum* and *longiflorum* are very much alike in general growth, and the treatment that would suit one will suit the other. They will grow and bloom well in the open air, but the foliage is sometimes damaged by wet and spring frosts; they appear to be hardier than *L. lancifolium album*, and not quite so hardy, but this may arise from their coming above ground earlier in spring. The principal injury is done when the plants first begin to expand their foliage, occasioned by wet lodging between the leaves and becoming frozen, by which their vessels are ruptured, and disease is the consequence. This shows itself in brown blotches on the foliage. A light sandy peat mould is the best soil for these bulbs.—*H. Groom.*

MELONS.—*Rusticola.*—We are at all times willing to answer reasonable questions, or even unreasonable ones, if it is possible; but we cannot print a treatise upon cultivating every sort of plant that our correspondents may inquire about, nor go, in these notices, into long discussions about questionable points of physiology. There are moreover certain things which all men interested in gardening are expected to know, and we can no more undertake to explain such matters than we can teach the A B C of reading. You had better consult some book on the cultivation of the Melon, unless you find an excellent article in to day's Paper sufficient for your purpose. As to the causes or supposed causes of disease, we trust you will get some information upon that point in leading articles during the present year. The mode of destroying Thrips mentioned at p. 649 of our last volume is this: dust the leaves of your Melons over with flowers of sulphur, and let it remain for a few days, then give them a good washing with the syringe.

NAMES OF PLANTS.—*A Rector.*—Epidendrum viscidum.—*F. J.*—Starjelly is probably the Nostoc commune, a gelatinous plant allied to Laver, the green slime of ponds, and similar productions. We *cannot*, however, answer your inquiry positively without seeing the substance.—*A. K.*—Hypnum sericeum, not cupressum. We cannot undertake to occupy ourselves in naming Cryptogamic plants.—*A Constant Reader.*—Erica bicolor.—*W Billington.*—Pyrola rotundifolia.—*G. Thompson.*—1, Geanera Douglasii; 2, 3, 4, Geanera bulbosa.

POTATOES.—*W H* thinks that because gardeners are often blamed for the bad quality of Potatoes which unskilful cooks cannot dress, therefore gardeners ought to be allowed to cook Potatoes themselves. We submit this proposition to the consideration of "W. H.'s" brother gardeners, who would, no doubt, be greatly flattered at being transferred from the garden to the kitchen. It strikes us, however, that it would be better to tell cook not to boil them in too much water, to give them a little salt, and when they are boiled enough to pour off the water, cover them with a cloth, and leave them on the hob to dry a little.

PRESERVING CUT-FLOWERS FRESH.—*A curious Observer* cannot do this beyond a very few days, by any process. To put them in a close tin box cannot have any other effect than that of rotting them. The water that was found when the box was opened resulted from the decay of the specimens.

RATS.—If as *Caledonian* will give us the information he offers we shall be obliged. It is not worth discussing questions of this sort. Facts, and facts alone, are useful.

ROOT-PRUNING.—*A B D.*—This must necessarily answer equally well with all over-luxuriant trees, if not overdone, as is sometimes the case. As for the Fig, in a climate like this, it should be so treated every year or two.

VERMIN.—*Poor Robin.*—Your plants are infested with Green-fly, which you must kill with tobacco smoke. You may also try gas water on those which are hard wooded, in the manner described at p. 445, 1843, but be cautious, for some things will not bear it. Blackbirds are easily caught in rat-traps, baited with Beans or Peas; that is the best mode of destroying them. It is of no use to waste time in popping at them, for they soon get too cunning to be had in that way.

VINERY.—*J J.*—We would try a good top dressing of superphosphate of lime, applied just when the buds are beginning to swell.

VINES.—*John Abel.*—The Muscat Escholata is the same as the White Muscat of Alexandria. The Escholata superba is perhaps the Black Muscat of Alexandria.

MISCELLANEOUS.—*A Correspondent.*—A list of the Horticultural Society may be had upon application to the Secretary.—*A Subscriber.*—You may head down Yews and Hollies now. The difference between Charcoal dust and rough pieces is this, that the latter keeps the soil open, and the former converts it compost—a very important distinction.—*Amateur.*—Epsom Marl will answer your purpose. Moles are only advantageous in compact soil which wants loosening. We do not know what good they can do on light well-drained land.—*A Subscriber.*—In the centre of p. 518 of your conservatory you may plant Lucelia gratissima.—*Anonymous* asks questions which require much time to answer, and therefore he must have patience, till we can find time to consider his inquiries.—*R T B.*—More warmth and less water at the roots will restore your Calceolaria to better health. Look to the drainage.—*W. S. S.*—We fear you have no remedy. At least it is not in London that the remedy can be found. Why not raise your seedlings yourself? It is the only way.—*Jacobite.*—We find a list of plants suitable for a flower-garden, all hardy, and showy, given at p. 613, vol. 1841.?—*Jessica.*—It is.—*Peter.*—We do not know any one who would exchange seeds for your Rhubarb.

*** An untold many communications have been received too late for answering this week.

ERRATA.—In the article on Rose, p. 27, col. 2, instead of "the stock hive," read "the stirred hive"—or hive with which to stir.—In the paper on Colour of Carnations, p. 31, col. 2, for the word of "The flowers were decidedly attractive, for it literally filled the garden without passing before them," read with Florist" &c.

[illegible]. — Price 12s. 6d., Mathematical [illegible] Instrument Makers, Survey Maps to direct the construction of Agricultural Drains to every requisite Level, Plans for laying out Pleasure Grounds, especially for Gardening. The private Gentleman, the Land Steward, and the Agricultural Engineer will alike find in it all that is desired. The Instrument is fitted in a case, and sent to any part of the country, [illegible] price 2l. 2s.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing in a time rapid vegetation in Plants than any substance known. It may be had at Mr. Lawes' Factory, Deptford Creek, price 7s. per cwt.

Phosphate of Potash	. . .	15d. per cwt.
" Soda	. . .	12s. "

The Agricultural Gazette.

SATURDAY, JANUARY 27, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Thursday, Feb. 1	Agric. Inq., Society of Ireland	6 p.m.
Wednesday, Feb. 7	Agricultural Society of England, Highland and Agric. Society	
Thursday, Feb 8	Agric. Inq. Soc. of Ireland.	

In the present Number of the "Quarterly Journal of Agriculture" there is an interesting paper by Prof. Johnston on "THE MANURING AND STEEPING OF SEEDS." The facts there recorded, and the manner in which they are shown to be what the known laws of Vegetable Chemistry and Physiology would lead us to expect, combine to render this a subject to which the experimental Agriculturist may usefully direct his attention.

The advantage of steeping seeds in certain chemical solutions seems to have been first pointed out by F. H. Bickes, of Castel, near Mayence. He announced his discovery in a lately-published pamphlet "On the Cultivation of Soil without Manure." Notwithstanding the extravagance indicated in its title, and which characterises it throughout, this publication records some surprising facts and testimonials on this subject; and these have lately been corroborated by the experiments of Mr. Campbell, of Dundee. A letter descriptive of the method of doctoring seeds adopted by the latter gentleman, and of their consequences as exhibited in the growing plants, has just been published in the Transactions of the English and the Highland Agricultural Societies—an extract from it will be found in another column. Mr. Campbell's experiments were performed upon seeds planted in the clay taken from eight feet below the surface of the ground; and though under such unfavourable circumstances, the Wheat plants from them tillered into five or eight stems, while those from unprepared seeds had only two or three stems apiece. *That*, however, which is broadly asserted in the German pamphlet is also hinted at by Mr. Campbell—viz., that steeping seeds in suitable solutions will render all future application of manure unnecessary. This is a statement which no practical farmer can for one moment entertain, and therefore we are glad that it is not necessary to suppose it to be true before we can believe that this process may sometimes be beneficially adopted.

It seems probable, that by some such means as those suggested by Messrs. Campbell and Bickes, the period of germination, which is one full of danger to the young plant, may in many cases be shortened; and this is very desirable, for, owing to the conversion of the starch of the seed into sugar, which is then proceeding, the plant is at that time liable to attacks from all sorts of vermin. In the case of the Turnip, especially, any means which would hurry it through this period into the rough-leaved stage of its growth would be most useful, as it is only when its leaves are still sweet that it is liable to the attacks of the fly.

But from the results of some of Mr. Campbell's experiments we may infer that the influence of his process extends into the future history of the plant much beyond the period of its germination; and it is on this account that we would recommend it now as a suitable subject of experiment for Wheat growers. The mineral ingredients of Wheat amount to about one-fiftieth of its weight; and, from the mere fact of their existence in the seed, it is probable that they exert an important influence over its germination and future growth. Any artificial addition to their quantity—and, by soaking Wheat in certain solutions we can *double* the natural quantity of its mineral constituents—will therefore increase that influence.

The following are the substances which, besides the four elements composing its organic structure, are to be found in Wheat:—soda, potash, lime, magnesia, sulphuric acid, phosphoric acid, silica, alumina, and chlorine.

It would probably not be difficult to dissolve in water such matter in such quantities that the solution should contain in their natural proportions all these mineral substances; so that Wheat, by being steeped in it, would merely increase the *quantity* of its mineral ingredients, without at all disturbing the balance among them which Nature has assigned; and perhaps this would be the best way of proceeding; but as it is interesting to know the individual effects and relative value of different substances we propose to try a series of experiments for this purpose, confining ourselves in each to the application of only one of the salts, in the form of which the above substances must be employed.

For those of our readers who may not yet have got in all their Wheat, for we by no means wish that it should be a mere garden experiment, we shall first state the plan we propose to adopt, and should our example be followed by any one, we shall be happy to report next autumn the results of his experiments, along with those of our own.

It is intended to soak for 48 hours previous to sowing, eight parcels of Wheat—say one bushel apiece—each in a solution, to be obtained by dissolving 5 lbs. of one of the following substances in such a quantity of water as may be necessary thoroughly to cover the seed.

The prices per lb., placed opposite these substances, are such as will be charged by any *wholesale* chemist of whom they may be ordered.

Silicate of soda	0s.	6d. per lb.	Phos. of ammonia	2s	6d per lb.
Nitrate . .	0	3 ,,	Sulphate . .	0	3 ,,
Sulphate of soda	0	3 ,,	Muriate . .	0	3 ,,
Phosphate .	1	6 ,,	Nitrate of Potash	0	4 ,,

The Wheat, after being thus treated, will be hoed in at the rate of two bushels of the dry seed per acre, in drills nine inches wide, and a ridge sown with Wheat in the ordinary way will be left as a standard of comparison between each couple of adjacent plots. The extent of the experiment, for those who may not wish to hazard so extensive a trial, might be reduced one-half without perhaps much impairing the value of its results.

WE have no wish to enter upon the question, WHAT WEEKLY SUM IS A JUST AND SUFFICIENT WAGE FOR AGRICULTURAL LABOURERS? nor shall we attempt to determine whether the consideration of such a question would be practically useful—whether, in fact, the lowness of wages is, in the long run, at all dependent upon the will of the employer; but there is one subject arising out of the relation existing between master and servant which we are anxious should be thoroughly discussed in our columns, and we shall therefore make a few remarks upon it, in order that others may be induced to take the matter up. We allude to the POLICY OF PAYING FOR WORK BY THE PIECE.

This mode of payment might be advantageously adopted more generally, and for many more farm-operations than it now is. During the past year we have paid by the piece for turning dung in the yards, for filling it into carts when ready for spreading on the land, for hoeing Wheat and other grain crops, Turnips, and other roots, &c.; for harvesting Corn, *i. e.*, cutting, tying, and stooking it; for pitching and loading the Corn in the fields on the cart, and pitching it to the builder on the rick in the stack-yard, and for harvesting all sorts of roots, *i. e.*, with respect to Potatoes, for digging and pitting them; and with respect to Turnips, Mangold Wurtzel, and Carrots, for pulling them, cutting off their tops, and loading the roots in one set of carts, and the leaves in another. If we except horse labour, the greater part of the work on the farm was thus paid for by the piece; and there is this advantage in this system, that activity and spirit on the part of the labourer are thus insured by the powerful principle—*self-interest*

It is of importance in certain complicated operations of husbandry, in which it may not be possible to manage it wholly thus, that at any rate *one* of the branches of which it consists should be paid for in this way By so doing—to take the case of the preparation of Turnip-land under drill-husbandry for the seed—the men at the dunghill who are loading the carts, being kept vigorously at work by self-interest, and all the other operations being dependent on them, those who are carting, the men who are spreading the dung in the drills, and even the ploughmen who are opening fresh drills and covering the dung in by splitting the old ones, are forced to proceed with proportional activity—an activity, too, which is not merely the result of necessity, but the consequence in some measure of interest in their fellow-workmen, whose wages depend on their keeping them fully employed. Similar cases to this occur at harvest-time, when those who pitch the corn to the cart and to the rick are paid by the acre of ground cleared, all the others being employed at day-wages; and in November, during root-harvest, when the profitableness of the contract taken by the men in the fields is made to depend a good deal on the activity of the boys with the carts, and of the men at the heaps, who pit the roots and thatch them, all of whom are working at day-wages.

The following are the prices we have paid for the above descriptions of work during the past year. The wages which the men actually made are placed opposite; and we must remark, that before any one can pronounce these wages to be too high, (we are willing to admit the price given was too high in one of the cases,) he must know what sort of men they were who earned them. 2s. 6d. seems a great price for a day's work of an Agricultural labourer, but it was earned by filling 40 cubic yards of manure into carts, which all men could not do:—

	Wages earned per day of 10 hours. Men.	Women.	Boys.
For turning dung and earth compost, 1st time, 3d. to 1d. per yard; for do 2d and 3d time, 2d. per yd.	s. d. 2 0		
For filling wall-made dung into carts, 7s. 6d. per 120 yards	2 6		
For hoeing Wheat, 2s. 6d. to 3s. per acre; for twice hoeing Turnips (singling them, &c.), 8s. to 7s. an acre	—	0 10	6d to 1s6d
For harvesting Wheat (cutting, tying, and stooking), 7s. to 8s. 6d. an acre	2 6—2s.	—	1s to 1s 6d
For pitching and building Corn on the carts in the field, and pitching to the builder on the rick, 1s. 6d. per acre	2 6		
For harvesting roots (pulling, cutting off tops, and filling them into carts)			
Turnips, per acre, 6s.	2 0	0 10	6d to 10d
Swedish Turnips, 8s.	2 2	0 10	6d to 10d
Mangold Wurtzel, 9s. to 10s.	2 6	0 10	6d to 10d
Carrots, 21s.	2 0	0 10	6d to 10d

The price paid for harvesting the Mangold Wurtzel, as proved by the wages earned by the men during a short November's day, is, we think, the only case in which too large a sum was given; though in the absence of knowledge of what sort of workmen the labourers were, those who have been accustomed to paying for work by the piece will be more likely to agree with us in saying so than those who have been hitherto accustomed to pay only day-wages.

There is one advantage in this system of payment for work, viz.—the independent feeling which it imparts to the labourer; he is then no longer *bound* to a master, unless his own agreement be considered in that light; and at the same time his master has, within the limits of that agreement, all the hold upon him which he would have under any other mode of payment.

The above prices are not stated as giving in our judgment the wages which farm-servants ought to earn; these necessarily vary with the capability of the men and the customs of the country. In discussing practical subjects of this kind, we are careful to avoid assuming a dictatorial style, for we are well aware, in the practice of the farmer, how principles which might seem of almost universal applicability are nevertheless entirely at the mercy of the varying circumstances of different districts. We have merely stated our experience in this matter, in the hope that our practical readers will enable us to publish theirs.

We had written thus far, when our attention was directed to a paragraph on this subject in Mr. Pusey's article "On the Agricultural Improvements of Lincolnshire," in the current Number of the English Agricultural Society's Journal It is from the pen of a Lincolnshire Agriculturist, and we quote it entire, as it entirely agrees with our own views of the subject. It will be perceived that the price given for loading manure is greater than that mentioned in the above table. Before, however, any inference can be drawn from this, we must know what sort of stuff the manure was, for it varies much in weight:—

"Whether 'task' work be more in practice in Lincolnshire than elsewhere, I, from my retired habits, know not; but it is a practice highly beneficial, both to the farmer and labourer; the one gets infinitely more work done, and the other more wages and better habits. For instance, in filling the carts with manure by the day, the labourer seldom fills more than eight or nine loads; whereas, for days together, this year, I had 160 loads of manure, each load 14 cubic yards, filled by 10 labourers at 1½*d.* per load, and spread upon the fallows with nine carts, nine horses, and nine of my own men, and generally finished by 2, never later than 3, P.M.—sharp work, of course, that the labourers push everything else on—no creeping; and they thus earn 2*s.* 4*d.* a day, and have ample time to do a little work in their own gardens in the evening."

ON THE AGRICULTURAL VALUE OF LAND.

(*Continued from p* 42)

ALTHOUGH it thus appears that few means of improving the texture of a soil are so efficient as drainage, yet there are cases where the faults in its mechanical properties are of a kind that drainage will not remedy. If a clayey soil have the water removed from it, by which every winter it was worked to a paste, and, therefore, every summer dried to a brick, it will undoubtedly be greatly improved—it will be made more friable: the land, however, will still be clayey. If, again, sandy land be wet, drainage, although it will improve the soil, will not make it heavier, its lightness will still be its fault. The only way to remedy this is, in the one case, to add lime, ashes, and other substances tending to make the land looser; and, in the other, to add clay, marl, and other substances whose tendency is to make the soil heavier

It is found in nature, and is the case in practice, that the more compound a soil is, the more valuable it is; that the fertility of a soil is, in a degree, dependent on the variety of its component parts. This may be because the merely *mechanical* properties of a soil, which consist of a

mixture of many earths, one layer, perhaps, three inches saturated by a mixture of only one or two. But however it is explained, it is a fact which is borne out both by the observations of the geologist and the experience of the farmer. When the soil overlying the junction of two rocks, whose mineral composition is different, appears to be owing to a mixture of the parts of each, it is always found to be more fertile than the soil on either side of it. Thus overlying the mineral composition merely of the one and the other the mineral composition merely of the other. This mixture of soils frequently takes place, especially where the strata of the two adjacent rocks are inclined, and the one thins out over the other. A very marked instance of increased fertility produced in this way occurs near Frampton-on-Severn, Gloucestershire, where the gravel thins out over the clay of the lias. The land on the former of these beds is valued at 25s. per acre; that on the latter, which is of a perfectly opposite character, is valued at 20s. per acre. There is a band about 30 yards wide between the two, where the gravel thins out over the clay, in which the soil is valued at 35s. per acre. These valuations were made by a committee of the farmers of the parish, for the purpose of apportioning a new rate; and the differences in them are evidently owing to a mixture, in the narrow band alluded to, of the clay on its one side with the gravel on the other.

But the advantage of such a mixture is not only attested by the geologist who observes in nature cases in which it is apparent, but it is recognised by the practice of the farmer.

In the fen countries, the soil on the peat is altered and improved by spreading over it the clay on which it lies. When this has been done twice or thrice the value of the soil is greatly increased; instead of being so light as formerly that it was blown about by the wind, it has acquired a firmness fitting it for the growth of Wheat and Beans. This means of improving peaty soils might probably be made use of more generally than it is, for the very formation of peat requires that its subsoil be clayey, or at least that it possess the retentiveness of clay; and the chief fault of peaty soils being lightness, the remedy is thus always at hand.

Another instance occurs of an artificial mixture of soils, and the advantage attending it is attested by the practice of the Norfolk and Suffolk farmer. It is a common practice there to remove the defects of the light sandy soil of the lower member of the plastic clay, by digging pits in the corners of the fields, and fetching thence the clay, and sometimes the chalk marl which occurs at a considerable depth, and spreading it over the surface, at the rate of 100 cubic yards per acre. This, though it is effected at a cost of 6d. a cubic yard, is productive of a most profitable result. The land, as in the case of the peat, acquires a valuable degree of tenacity. In Bedfordshire, also, and over the whole extent of the district on the new red sandstone formation, it is a practice to dig the red marl which lies at no great depth, and spread it over the soil, which is a stiff gravelly clay. The difference here between the substances thus mingled is not so great as in the other cases, but is sufficient to render the operation profitable. There are many other cases in which an advantageous admixture of soils might be effected, and in which the subsoil-plough, which has the effect of gradually mixing the soil with the subsoil, might be used with advantage. In natural cases of mixture, such as those already alluded to, where a rock of one description thins out over one of another kind, a more thorough mixture of the ingredients of each might be effected by this implement to the depth of at least 18 inches. In those cases, again, where the subsoil is composed of beds of different material alternating with one another, a mixture of these could be effected to a similar depth in a similar manner. Thus, one of the members of the old red sandstone series consists in some places of alternating beds of clay and sand; and the soil is sandy or clayey, according as it is above the one or the other. It is full of water, which accumulates in the sandy strata and gets its way to the surface by rising over the edges of the beds of clay. In this case the improvement consequent on the use of the subsoil-plough after drainage would be immense; the surplus water would not only be taken away, but the soil itself would be altered, the sandy and clayey strata would be mingled.

The fertility of an alluvial soil which is formed at the mouths of large rivers by the subsidence of the earthy and vegetable matter carried down by them, is owing not only to the fineness of the particles of which it is composed, but also to the circumstance that it is composed of particles of a variety of rocks—of all those, in fact, through which the bed of the river passes, and is therefore generally a mixture of every variety of earth.

The mineral composition of a soil influences its value also, inasmuch as on it depends, in a great measure, the expense of working it. This, of course, is the case only on arable lands, but there, the labour on a clay soil is immensely greater than the labour on a light sandy soil. And it is evident that though in both cases the amount of grain produce were the same, yet on estimating the expense of labour, the value of the two products would be less in the one case than in the other.—*M.*

(*To be continued.*)

MANX AGRICULTURE.—No. II.

Considering the size of this island, the soil evinces more than might be expected. The soil of the northern extremity is strong and deep, well adapted for Wheat and Beans, and valuable crops of the former are in favourable seasons generally obtained. In this portion, also, a large extent of deep alluvial soil occurs, and excellent marl may be obtained, but the latter is not so much used as it would be under equally favourable circumstances by British farmers. In practice it is not found to act as immediately as elsewhere, if used on the land under which it is found; and not only is it too heavy to bear the expense of land-carriage to distant farms of lighter soil, but the nature of the tenures would for the most part render it illegal to remove it. The soil in the south is very different but hardly less valuable; and as the owners generally farm their own lands every advantage is gained which careful farming, adequate capital, and modern improvements can bestow. In the south are the only lime quarries which exist in the island, and from these kilns excellent lime is procured at a cheap rate—a two-horse cart-load for about 5s. The southern shores are also most prolific in casting up "wrack" or sea-weed, which is drawn away with great avidity and industry. This is generally put upon the Wheat and Oat stubbles during autumn and winter, ploughed in while yet fresh, and without any additional manure the Potatoes are planted in spring. The Potato crops thus managed, are generally good, averaging 30 and often reaching nearly 40 bolls (each boll being 4 cwt.) per acre. The sea-weed is not considered permanent manure, and can seldom be relied upon for more than one crop; it is not, however, an uncommon circumstance for a large farmer in the south to wrack the whole of his Potato land, and be thus enabled to bestow the farm-yard manure upon his Turnip crop. As before stated, the usual rotation of crops adopted is that under the four-course system, breaking up the Grass or Clover leaf or Oats, these being followed by Potatoes, and the Potato land being subsequently limed (by some, when the Potatoes appear in rows above ground, by others after the crop has been removed) for the succeeding Crop of Wheat or Barley, according to the quality of soil, or the speculative spirit of the farmer.

The species of Potato generally planted for the main crop is that called "Cups." It is a prolific and hardy variety, and bears a good character in the Liverpool and Manchester markets. Upon inland farms the most of the yard manure is bestowed upon the Potato crop, so that their Turnips are generally raised upon bone-dust, with or without vegetable ashes. During the last two years large quantities of guano have been imported from Liverpool, and this useful manure, when prudently applied, has been found admirably adapted to the Manx soils. How far it may be trusted for the succeeding crops of grain and Grass seeds is yet, perhaps, hardly ascertained; but there can be little fear of their succeeding if at least one-half of the Turnip crop is consumed on the land. The Barley is generally sown in spring with Grass seeds; Winter Barley is a variety little known or used in this island, although I have no doubt it would succeed, favoured as it would be by our mild seasons. Amongst other fiscal privileges with which the island is endowed, it is most happily free from those oppressive excise laws, which, especially as regards the malt duty, cramp the energies and lessen the profits of the British farmer. Every brewer is, and any farmer may be, his own maltster; and the home market for Barley (although greatly depressed by the recent tariff) is generally steady and fairly remunerative. In the management of the Hay crop the Manx farmer is culpably deficient. The Grass is generally allowed to shed its seed before it is mown, and if not exactly over-made, it is at all events allowed to remain in cock until, by the alternate influence of sun and rain, the nutritious properties have been for the most part wasted away. The lea generally continues two years, being mown one year and grazed the other, when it is broken up to receive the Oat-crop, which recommences the course.

As part of the course of cropping it may be proper to mention (now that increased attention is being invited to the subject in England) that it is generally the custom of the native Manx farmer to raise a small annual crop of Flax, but for domestic purposes only. The value of the seed for cattle feeding, and of the steeping fluid as liquid manure is little known, and perhaps never made use of, indeed the Flax is generally pulled before the seed-pod is ripe. At a former period much attention was paid to this crop, and previous to the decline of the Irish linen trade it was considered remunerative. The deep peaty soils of the "Curragh" land are admirably adapted to its successful cultivation, and if the value of the fibre is in some degree deteriorated by the ripening of the seed-pod, yet that loss would, it is believed, be amply counter-balanced by the value of the boiled seed for cattle-feeding, or of the raw seed for the next sowing.

In continuing this sketch of the Agriculture of the Isle of Man, it will remain to give some account of the live stock bred or imported into the island, of the implements of Agriculture—the average rents of land—the forms of leases—and of prices and quotations of markets, and to notice some peculiarities of tenure which exist.

It will, moreover, be only fair towards the English reader, and in no way unjust towards Manx Institutions, which are not conceived in the spirit of modern English legislation, and indeed are lamentably destitute of the principles of civilization (excepting those of the feudal age), to impart some information respecting insular laws, customs, and privileges, which exist only for the benefit of the natives, and are oftentimes used as cruel engines of oppression and inhospitality towards the stranger who may settle amongst them.—*Cutler.*

(*To be continued.*)

ON MINERALS, INORGANIC MANURES.—No. IV.

By Professor Charles Sprengel.

(*Translated from the German.*)

As lime possesses all the above qualities only in the caustic state, it follows, that in order that the manuring with lime may produce the greatest effect, it should be

are, how to be counteracted. Can its known fluxes, such as coal, &c., in this case produce the effect of magnesia, which does not convey so much magnesia to the plants, containing less of it than the neutral salt. It is also said that the manuring with lime has produced a very beneficial effect on soils which have been applied by the Bicarbonate—which, if confirmed, is to be ascribed to the formation of proto-humate of magnesia.

We shall always find that the manuring with lime will be most useful on those soils which contain but little of it. This is easily explained, as most cultivated plants require much lime for their nourishment. It is true, that a soil on which the burnt lime is of much use may yet contain some lime in its natural state, but the latter will be found to be mostly a silicate, which is of no avail to plants, as it is soluble neither in water, humic nor carbonic acids; or such lime is in the state of a carbonate of lime, which latter, again, decomposes only in a very small degree the coal of humus or the vegetable matter of the soil; the carbonate of lime, moreover, is not soluble in pure water, but solely in such as contains much carbonic acid. In soils after all, which contain close under their surface, chalk or marl, the manuring with lime will be of little or no use at all, which is easily accounted for by the deep-rooted plants (though they be merely weeds) conveying a sufficient quantity from the subsoil into the furrow-slice. It is asserted that the manuring with lime is injurious on fields which slope much towards the north. I confess that I cannot explain this. Perhaps there are other causes which here come into play; still, it would be interesting if those who have made this observation would bring their experience on this subject before the public.

(To be continued.)

ON THE ECONOMY OF STALL FEEDING.

In a lecture on the fattening of cattle, delivered to the Royal Agricultural Society, and reported in the *Gardeners' Chronicle*, I stated that some experiments were then in progress at Whitfield Farm, through the kindness of Lord Ducie, which I believed would confirm some of the theories adduced in that lecture. I now beg to redeem my promise of communicating to the public the results of these experiments. They were carefully superintended by Mr. John Morton, from whom I have received much assistance on this and on many other occasions.

Liebig, in his work on Animal Chemistry, has defined more accurately than any preceding writer the source of animal heat, and the constituents of the food used in its support. He has shown that warmth is an equivalent for food, and that cold, on the other hand, renders necessary a greater supply of food, by carrying off rapidly the heat which its combustion engenders. He has also pointed out that motion is always accompanied by a waste of matter in the body, and it followed naturally from this that an economy of food was necessarily the result of an economy of motion. The experiments of Lord Ducie and Mr. Childers, upon feeding sheep in sheds, afforded a powerful practical illustration of these theories. The warmth communicated by the sheds was equivalent to a certain amount of food, and the deprivation of motion occasioned a diminished waste of the tissues of the body, and, therefore, a corresponding saving of aliment. To illustrate these views more fully the following experiments were instituted on five lots of sheep, each lot consisting of five sheep:—

No. 1 lot was fed out of doors, and was therefore exposed to all the influence of atmospheric changes.

No. 2 lot was kept under an open shed, and therefore was less exposed to the inclemencies of the weather.

No. 3 lot was placed under an open shed, similar to the last lot, but in this case the sheep were kept solitary, *i. e.*, each was confined to a space of 3 ft. by 4 ft.

No. 4 lot was placed under a close shed in the *dark*.

No. 5 lot was kept under a shed like No. 4, except that each sheep was separated, and confined to a space of 3 ft. by 4 feet.

These different lots were allowed 1 pint of Oats for each sheep per diem, but were supplied with as many Swedes as they felt disposed to eat; the weights consumed were accurately determined. The live weights of the sheep were ascertained before the commencement, and at the conclusion of the experiments the results were as follows:—

Lot.	Live Weight, Nov. 15.	Live Weight, Mar. 9.	Increase in Live Weight.	Weight of roots eaten.	Increase in Live Weight for each 100 lbs. of roots eaten.
1	598 lbs.	1078 lbs.	480 lbs.	1912 lbs.	1·2 lbs.
2	584	1098 3-4ths	514 3-4ths	1794	1·6
3	600	1130 1-4th	530 1-4th	1838	1·6
4	592	1129 1-4th	537 1-4th	1695	2·1
5	611	1218	607	2060	2·4

In the consideration of these experiments, we may refer to the "roots" alone, as the quantity of Corn supplied to the sheep was in all cases the same. It will be seen that the first lot, or that which was exposed to the cold, ate about three hundred weight of food consumed by the sheep fed in a dark warm shed. Exposure to cold thus abstracted heat so rapidly from the bodies of the sheep, that a large amount of food was necessary to supply that power to the tissues. That abstraction of food was wholly employed for this purpose, and entirely lost so far as the farmer is concerned, is obvious, for the absolute increase in weight of the first and last lots is nearly equal, although the relative increase for the food consumed is much in favour of the latter. Thus, also, it will be seen that although the second lot of sheep received 3·5 lbs. of roots less than the first, yet that lot received a little more than the first relatively to their consumption of roots. The second lot, consisting of sheep fed in a shed, with shelter, did not require so much food to keep up the animal temperature of their bodies as the exposed sheep. The third two sheep, both lots were similarly situated with regard to exercise. In lots 3 and 5, a diminished space was afforded, but without advantage, probably from disturbing the placid temperament of the animals, as they were observed to fret and lose their appetites when thus separated. The result attending the experiment with the 4th lot is highly interesting. The sheep forming this lot were confined in the dark. In this state there were no inducements for the sheep to move about, or even to remain in a waking state, except when impelled by hunger to eat food. Hence they passed much of their time in sleep. During sleep, the voluntary motions ceased, and there was small waste of the tissues of the animal, which now possessed almost entirely a vegetative life, and increased rapidly in size, with small consumption of food. Although eating considerably less than one-half of the food consumed by those sheep which were exposed to the weather and to the causes of waste produced by voluntary motion, this lot increased nearly as much in absolute weight at a relative economy of food nearly three times as great.

The results of these experiments are very favourable to the views brought forward in the lecture referred to. They will, I trust, confirm, if proof be still requisite, the economy of stall-feeding, and the principles on which this practice depends. I am quite aware that considerable evils have been found to attend the system in certain cases; but in every case which I have examined, the evils seem wholly attributable to the manner in which the system was carried into operation, and not to the system itself. Cattle are confined in sheds built without any regard to ventilation or cleanliness; they become diseased; and stall-feeding is pronounced by the farmer, who thus suffers the effects of his own want of care, to be very injurious, and to be productive of evil consequences to the health of his stock. If cattle are exposed continuously to an impure atmosphere, the tone of their system becomes depressed, and disease follows, sometimes exhibited in the form of diarrhœa, frequently of rot, very often of consumption, or of one or other of the many diseases to which cattle are liable. But none of them are the results of the system, nor have they occurred when due regard has been paid to cleanliness and ventilation. These are points which retard the progress of fattening much more than farmers are generally aware of. Attention to these circumstances would, I feel convinced, render more sure the favourable results which follow from the communication of warmth and the deprivation of excessive motion, and would be further productive of economy in the returns for food supplied.—*Lyon Playfair, Royal Institution, Manchester.*

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. III.

(Continued from page 43.)

Thus we see how easily, with a little care and attention to experiments, a series of standards of the fertility of soils might be established. The same principle would apply equally to chalky or peaty soils. The amount of carbonate of lime indicating the former, and of vegetable matter the latter. But as the greater experience of others will not fail to suggest them, I refrain from mentioning standards by which the fertility of these soils may be easily fixed. The fertility of all soils is relative. One will produce a good crop of Corn, and a bad one of Turnips, and another *vice versâ*. This difference is almost entirely owing to the disproportion of impalpable matter and siliceous sand, and in many cases it is irremediable, except by a very considerable outlay of capital. Thus, in the heavy soil which I have mentioned above as containing 108 parts of impalpable matter to 187 of sand, to make it a workable soil it would be necessary to reduce the 108 by at least 10 per cent., and raise the proportion of sand as much.

How is this to be done? exclaims the intelligent owner of the soil. Where is the value of a science which describes to me a disease, but fails to suggest a remedy? In answer to these queries I would observe, that the first step towards the cure of a disease is to investigate its nature. If the disease is beyond remedy in its severe forms, it may be quite manageable in its milder stages. So it is with Chemistry as applied to Agriculture. Though it might be impossible in the above case to carry on to the land sufficient sand, to raise the elements of the soil to workable and fertilizing proportions, it would be by no means difficult to do so were the difference less, in districts where the material could be obtained. It is a well-known common practice to carry clay on to light lands where the impalpable matter which contains the aluminous earth is deficient. The utility also of carrying marl on to heavy soils is well known. Now marl, which is an impure carbonate of lime, can only be of use in two ways, either by rendering the texture of the soil looser—an important means of admitting moisture and air into the interior of the land—or it may be useful by absorbing moisture which contains ammonia, and thus indirectly contributing to the support and nourishment of the plant. A small amount only of the carbonate of lime (chalk or marl) is absorbed by the roots of the plants, and the experiments of Chemists have proved that the carbon necessary for the support of plants is derived from the carbonic acid of the atmosphere, and not from inorganic matter in the soil.

On the contrary, silicate of potash or soda is essential to the growth of Corn and Grasses so that, when it is practicable, much greater benefit may be presumed to be derivable from mixing sand instead of chalk with heavy soils. Farmers will sometimes go a long way for chalk, when they could obtain sand much more easily. In Horticul-

ture the use of sand is well known—why not attempt to carry out the principle upon which it is used upon a grand scale? I ought to mention that the whiter the sand the better, as the red sands sometimes contain more oxide of iron than would be useful; but this need not deter any one from trying the experiment, as clay soils are generally deficient in oxide of iron, a small portion of which is necessary to the growth of plants.

The importance, then, of obtaining, by correct analysis, the proportion of sand and impalpable matter is very apparent; and this knowledge may be obtained by very simple means. I will principally confine my observations on this part of the subject in detailing these means. Let Agriculturists only acquire the habit of scientific inquiry, and the more minute processes will become easy and familiar.

I propose then to detail the method of distinguishing the following properties in all soils:—

Firstly—Their retention of moisture.

Secondly—The amount in a given quantity of soil, of coarse sand and undecomposed vegetable fibre.

Thirdly—The proportion of fine sand.

Fourthly—The proportion of impalpable matter.

The apparatus necessary for this analysis are:—

1st. A pair of small scales and weights.
2d. A spirit-lamp.
3d. A glass funnel and filtering paper.
4th. One or two Porcelain crucibles well baked.
5th. An iron stand and glass rod.
6th. A small pestle and mortar.
7th. A graduated half-pint glass measure.
8th. A phial of muriatic acid.

Any Chemist will supply these at a small cost. They might be fitted into a box and sold together. The operator must then proceed as follows:—A portion of the soil to be examined must be taken from a few inches beneath the surface, and exposed to the air in the sun until it becomes sensibly dry. Four hundred grains, or any convenient amount, must be now carefully weighed, and exposed to the heat of the spirit-lamp, a small piece of dry wood or chip being placed at the bottom of the vessel.

With his glass rod the operator must stir the soil about until the chip becomes charred, when the application of heat must be discontinued. The crucible being allowed to cool, the soil is now to be weighed and the loss of weight will indicate the amount of moisture. This is a very important characteristic of soils, as their fertilizing properties are well known to be much influenced by their power of retaining moisture.—*C. R. Bree, Bloomsbury.*

(To be continued.)

Home Correspondence.

Manure Dropped in the Field.—I take the liberty of submitting a few remarks on the national as well as individual advantage that might be derived from fully carrying out a method which I have practised for some years, and which I will call—an economical mode of applying that portion of manure upon a farm which is in a great measure annually lost for want of knowing how to make the most of it. I have read most English writers on the various ways of preparing and applying manures, but among them all I have not seen a single remark on the method which I have for some years put in practice, with much advantage to myself, and which I am quite sure would, if generally adopted, be of great benefit to every occupier of land. It is obvious to every one who knows anything at all of the matter, that in pasture land, where horses or other cattle are kept, the greater part of the dung voided by these animals is entirely lost, so far as the real improvement of the land, or the increase of such herbage as the cattle will eat, are concerned. In the heat of summer it is mostly dropped under trees, and near hedges or plantations, and in the places where the animals resort for shade; and in the latter end of autumn and in winter, in similar places, where they lie the greater part of the night for shelter. It is because of this that the Grass in such situations is very rank and unpalatable; in fact, it is scarcely ever eaten by either cow or horse, but gets trampled upon, so that much herbage is wasted. In meadows, the Grass in such places is generally so very rank, and so much earlier than in other parts of the field, that it gets lodged and spoilt before the rest of the field is ready to be mown. Much the same result will occur if the land be in tillage, as it causes the crops to grow too rank and to lodge, so as to be of little value; hence the richest land becomes of no real value to the occupier. To prevent such waste, I recommend the following simple method, which I know to be beneficial from long experience; it is not theory that I am advocating. In the spring of the year, when the cattle first go out to Grass, and their dung is thin, I generally carry a broad shovel with me when I fetch them in or take them out for milking, and all the dung which after lying down they drop in one heap, I spread out as wide as it will go, so that when covered one superficial foot I make to cover two or three. I thus manure double or treble the space that would be manured if the droppings were left as they fell from the animals; and instead of the herbage on these spots being lost for the season, or rendered so rank that nothing will eat it unless forced by scarcity, it will all along be increased in quantity over a larger surface, and will be beneficially consumed, the land being thus enabled to carry more stock through the season. When the dung is harder or crusted over, it can be spread out with the foot or, in case of slight frost towards the latter end of the year, it can easily be removed to a fresh place, where most wanted, to be there spread out as I have recommended. The dung of horses is of a different nature from that of cows, and sooner loses its fertilizing properties; the heat of the sun soon evaporates its moisture, and insects extract its rich juices, so that in a few days it

becomes like dry chaff, almost useless as a manure. To prevent this, I trust or beat it hard down with a shovel, and if of a large size spread it out a little first; this consolidation prevents the flies from penetrating it for the larvæ, and hinders waste by evaporation. By this method an amount of benefit may be realised from the summer-made manure in the field, nearly equal to what is obtained from cattle fed in the house. After it has lain in that state some time, and after it has enriched the ground and herbage, the hooks generally come—often too soon—for the grubs and earth-worms, and scratch it about, so that without any manual labour we have the benefit of confined turnpiking in very short space of time. But, as I have before said, it often happens that the dung is voided where the herbage is already too luxuriant; in such cases it should be removed entirely to a bare and poorer spot, and spread and compressed as before described. I have observed that horses are more apt than other cattle to drop their dung on long grass and on moist places; wherever this is the case it should be removed to a drier and more barren spot before it does an injury. By constantly following such a practice as this, it is obvious that in the United Kingdom many thousand acres more than those now so treated might be annually enriched, on which, it is evident that much more stock could be kept, and as there would be more manure for the arable land, there would be a great increase of grain and root crops. By taking away the surplus manure from places where it wastes and does injury, those spots become of greater value to the occupier; the herbage would become sweeter for all kinds of stock, and there would only remain the middle of the fields to be manured from the farm-yard or compost-heap. When a field is too rich, as in some instances is the case, it would be advisable to collect the dung of cattle and appropriate it for other purposes, for it is manifest that so much herbage and grain as is annually wasted, from over-luxuriance, is a national as well as individual loss. If noblemen, gentlemen, and landed proprietors could but be induced to adopt in their parks and grounds the practice I have thus recommended, it would soon become generally known, and, if practised systematically by all who have the means, it would soon increase the vegetable productions of the country to a very considerable extent.—*W. Billington, Underhill, Quoxetry, Salop.*

The Rooks.—At a meeting of proprietors, farmers, and others, called by advertisement in the Dumfries newspapers, to consider the most effectual means of putting a stop to the serious injury done to crops, &c. by the increasing number of Crows in this district of the country, various gentlemen stated the cost they were put to in protecting their crops from the ravages of the Crows, and the damage they sustain, notwithstanding all the care and cost they are able to bestow in preventing it. From these statements it appears that many farmers are at the present time paying, and find it necessary at other seasons of the year, particularly during the braiding of Wheat and Potatoes, to pay several persons for herding and keeping off the Crows, and that during several months in the year. That the damage actually sustained, over and above the expense of herding, by the ravages complained of, amounts to upwards of 4000*l.* annually. The meeting unanimously resolved—that while they did not pretend to say whether Crows may be productive of benefit, while kept within proper numbers, by destroying grubs and other insects, they were satisfied that a great excess of numbers at present exists, and that much serious loss and damage is the consequence. And that with a view to remedy this evil they respectfully but very earnestly entreat that those gentlemen who have rookeries upon their estates will either themselves cause the increase of the numbers in their rookeries to be prevented in time to come, by such methods as they may deem most expedient and effectual, or permit the committee named by this meeting to take the necessary measures at the proper seasons.—*Annandale.*

The Markets.—I inclose the return supplied by a widely circulated provincial journal, in which you will see malting Barley quoted at from *33s.* to *37s.*, while in the *Agricultural Gazette* of Saturday last the highest quotation is *32s.* for the same article. The best evidence, however, of the incorrectness of this report, is the fact that the average return of Barley for the week ending the 5th of January is given at *32s. 7d.*, while the highest price quoted in the *Gazette* in its *Mark Lane* report of the 5th, is *32s.*, with this observation annexed—"malting Barley continues in demand at Monday's quotations."—*D.* [In answer to our correspondent, we have only to say that the names of the parties furnishing market-reports are the only sureties we can possibly have for the accuracy of those reports; Messrs. Kingford and Lay are the parties who furnished the report which he has animadverted on, and we doubt not but they would tell us that the various qualities of Barley at the prices they named.]

Berberry Blight.—I beg to thank "A Moorland Gardener" for his interesting account at p. 12 respecting the Berberry blight. His statement contains much both for and against the opinion that Berberry blights Corn. May I be allowed, however, to observe, that perhaps "A. M." was too young at the time he ate "a mouthful of Berberries to notice that the leaves he pulled them from might be infected by two kinds of blight, one a fungi fungus, the other a light mealy one, similar to mildew seen on Hawthorn hedges. If the former opinion has an evil influence on Corn, it is strange why the opinion should be so prevalent amongst farmers all over the country. Lately I had some conversation on the subject with J. Cully, Esq., who stands high as a Norfolk Agriculturist, who informed me that he once had a large Berberry bush in his garden, and when there happened to be Corn in the adjoining field it was always mildewed near the bush, but was not so after the bush was destroyed.—*J. Wighton.*

Means of Improving the Quality of Manure.—Upon extensive farms, which consist almost entirely of arable land, there is necessarily a large portion of the straw that cannot receive much aid from the dung of animals. This is commonly denominated muck, and when applied to the soil proves but a weak manure; consequently, in converting it out, much labour is expended to produce small results. I am myself subject to this difficulty, and wish to devise means for improving the quality of that portion of my muck which cannot be used in the cattle-stalls or sheep-fold. I venture, therefore, to solicit the insertion of this letter in your *Agricultural Gazette* with a view to obtain answers from your correspondents to the following questions:—1st. Supposing the muck were formed into large manure-heaps, and during such formation one of the fertilisers now in use were added thereto—which of them would be most effectual in producing the desired result? 2dly. Whether such a mixture of muck and other matter would be a better application of the ingredients than if the muck were applied to the soil in the usual way by itself, and the fertiliser also by itself, drilled with the seed for the intended crop?—*R. C.* [Instead of answering this letter, as usual, among our "Notices to Correspondents," we insert it here, in order to elicit from our readers statements of *experiments* or *observation* on the important subject to which it refers.]

Experiments with Manures.—[I beg to notice that the lawn on which one experiment was made, has been under the scythe from 14 to 15 years; the soil is of a light sandy nature, over a layer 10 or 12 feet deep, of brown sand, which is superincumbent upon a bed of clay. "It will be seen by our April experiment, that 3½ oz. guano, per yard, produced a greater weight of Grass than that which had 4 oz. per yard; this result rendered it desirable to ascertain whether 3½ oz. per yard was the maximum for land such as this trial was made on. Our committee, who have taken a warm interest in this matter, suggested that another trial should be made: the result is now before you; and though the season was far advanced (21st July and 4th August) and the lawn repeatedly mowed before the manure was applied, the effect of the guano and nitrate on the hungry soil was truly surprising, for during the sultry month of September, the portion done over with guano and nitrate formed a striking contrast in colour and luxuriance to the surrounding sward. This trial showed a gradual increase in the produce up to that which had 7 oz. of guano to the yard; but I found 7 oz. too strong a dressing; it has a tendency when first applied to scorch the sward, and the decrease in weight in the portion done over with 8 oz. results from the latter cause. I mixed the guano with more than double its weight of ashes, which were made from prunings and other refuse on the premises.] The subjoined particulars refer to an experiment which was made on one of the lawns in the Botanic Garden, Manchester, with Guano, Nitrate of Soda, and Granulated Compost, on the 27th April, 1843. The grass was mowed and weighed on the 29th June:—

	Rate per Acre. Produce. Grass.	Manure. Guano.
	tons. cwts. lbs. oz.	cwts. lbs. oz.
The produce of 1 square yard, on which 1 oz. Guano mixed with ashes was spread, weighed 3 lbs.	6 9 72 0	2 78 8
The produce of 1 yard, on which 1½ oz. Guano mixed with ashes was spread, weighed 3 lbs. 2 oz.	6 15 5 0	4 5 12
The produce of 1 yard, on which 2 oz. Guano mixed with ashes was spread, weighed 3 lbs. 11½ oz.	8 0 78 12	5 45 0
The produce of 1 yard, on which 2½ oz. Guano mixed with ashes was spread, weighed 4 lbs. 4 oz.	9 3 74 0	6 24 4
The produce of 1 yard on which 3 oz. Guano mixed with ashes was spread, weighed 4 lbs. 11 oz.	10 2 63 6	6 11 8
The produce of 1 yard, on which 3½ oz. Guano mixed with ashes was spread, weighed 5 lbs. 14 oz.	12 13 99 0	9 50 12
The produce of 1 yard, on which 4 oz. Guano mixed with ashes was spread, weighed 4 lbs. 10 oz.	9 19 92 0	10 90 0
Hay.		
The produce of 21 square yards, on which 30½ oz. Guano mixed with ashes was spread, weighed 69 lbs. 1½ oz. The same, when dry or made hay, 24 lbs. 2 oz.	2 9 60 0	3 102 7
The produce of 21 yards, on which 7½ oz. Nitrate of Soda mixed with ashes was spread, weighed 36 lbs. 6½ oz. The same when made into hay, weighed 17 lbs. 1 oz.	1 15 35 0	0 107 13
		Gran. Compost.
The produce of 21 yards on which 42 oz. Granulated Compost was spread, weighed 42 lbs. 6 oz. The same, when made into hay, 13 lbs. 2½ oz.	1 11 19 0	5 42 12
The produce of 21 yards, without manure, 27 lbs. 14½ oz. The same, when dry, 13 lbs. 6 oz.	1 7 89 0	
	Grass.	Nitrate of Soda.
The produce of 4 yards, on which 1 oz. Nitrate of Soda, mixed with ashes was spread, weighed 16 lbs. 4 oz.	5 10 99 8	6 74 10
The produce of 4 yards, on which 1½ oz. Nitrate of Soda was spread, weighed 11 lbs. 8 oz.	6 6 21 4	1 1 7
The produce of 4 yards, on which 2 oz. Nitrate of Soda mixed with ashes was spread, weighed 14 lbs.	8 2 6 0	1 99 4
Fall of rain in May,	3.10	
do. in June,	1.90	
	5. inches.	

Result of a subsequent trial of Guano and Nitrate of Soda, which was made in the Botanic Garden, Manchester, on the 21st July, 1843. The crop was mowed on the 24th Oct., is dried, and kept in separate lots for the inspection of gentlemen who may feel disposed to examine it:—

	Rate per Acre. Hay.	Guano.
	tons. cwts. lbs. oz.	cwts. lbs. oz.
The produce of 21 square yards, on which 2 oz. Guano per yard mixed with ashes was spread, weighed 8 lbs. 2 oz.	1 10 72 12	2 11 8
The produce of 21 yards, on which 4 oz. Guano per yard was spread, weighed 16 lbs. 13 oz.	3 6 96 6	4 22 0
The produce of 10 yards, on which 4 oz. Guano per yard was spread, weighed 11 lbs. 5 oz.	2 6 99 4	13 66 8
The produce of 10 yards, on which 6 oz. Guano per yard was spread, weighed 11 lbs. 8 oz.	2 9 72 0	13 22 0
The produce of 8 yards, on which 7 oz. Guano per yard was spread, weighed 8 lbs. 11½ oz.	2 13 69 10	13 161 8
The produce of 8 yards, on which 8 oz. Guano per yard was spread, weighed 8 lbs. 11 oz.	2 13 5 11	21 66 0
The produce of 10 yards, without manure, 4 lbs. 11 oz.	1 0 28 12	— — —
		Nitrate of Soda.
The produce of 2 yards, on which 2 oz. Nitrate of Soda per yard was spread, weighed 7 lbs. 2 oz.	2 99 12	5 46 0
The produce of 2 yards, on which 3 oz. per yard Nitrate of Soda was spread, weighed 8 lbs. 4½ oz.	2 9 33 10	6 11 8
The produce of 2 yards, on which 4 oz. Nitrate per yard was spread, weighed 8 lbs. 5 oz.	2 9 109 4	10 90 0
The produce of 2 yards, on which 5 oz. Nitrate of Soda per yard was spread, weighed 8 lbs. 6½ oz.	2 11 106 2	12 56 8
The produce of 2 yards without manure, weighed 15 oz.	1 0 28 12	— — —
The following trial was made on the 4th August with a new description of Guano, from the Cape of Good Hope, which was reported to contain 40 per cent. of animal matter; the Grass was cut on the 24th Oct.:—		African Guano.
The produce of 2 yards, on which 1 oz. Cape Guano per yard was spread, weighed 1 lb. 2½ oz.	1 4 110 2	2 78 8
The produce of 2 yards, on which 2 oz. Cape Guano per yard was spread, weighed 1 lb. 5½ oz.	1 9 3 14	5 45 0

Salt.—Some time ago there was published "An Address to the Landed Interest on the Important Discovery of the Decomposition of Salt for the purposes of Manure, by Henry Kemp." In that address we are told that "The multiplied varieties of the culinary and flower-garden have also borne witness to the general efficacy of prepared salt, and though I am aware that the superior culture usually bestowed on these departments hinders them from offering so unequivocal a test as fields that are worn and exhausted by Corn, yet the superior health and vigour of everything to which it was applied in the garden afforded the strongest evidence for concluding that its agency may be as universal as dung, or any other great assistant of vegetation." In another place it is said, "The Salt produces one-third more of Corn than the best dung, and its cost is only about 10*s.* per imperial acre," but how to decompose the Salt appears to have been a secret. Has that secret been revealed yet? In those instructive articles in the 1st vol. of the *Chronicle*, named "Rural Chemistry," we are informed how Salt can be decomposed, how to convert it into a sulphate, and from that into a carbonate. Has Mr. Kemp any other method of decomposing Salt? Perhaps it may not be uninteresting to ask if the word Salt in the Bible has always a reference to common salt—the muriate of soda. We are informed that the term Salt was originally employed to denote common salt, but was afterwards generalised by chemists and employed by them in a very extensive and not very definite sense. They understood by it any body that is rapid, easily melted, soluble in water, and not combustible, so that it represented a class of substances midway between earths and water. We are also told that the carbonate of soda is found in Syria and other places on the surface of the ground, and that it has often the appearance of a rough dusty powder of a grey colour and alkaline taste. When reading the works of some of our Divines, there are two things we learn; the first is that they fancy themselves very good at explaining a text, however far the explanation be irreconcilable with the context; and the second is, that they endeavour to expound God's Word without knowing a very great deal about His works. When some of them speak about Salt or saltness, it appears to be synonymous with barrenness; and then we are referred to Pliny, Calmet, and Volney, as describing the land about the Dead Sea and other places, as barren from the quantity of salt it contains, and that no bird can fly across the Dead Sea, or animal live in it, and that its waters are bitter to the taste. Some of these statements could be answered with great certainty. In an essay read before the Literary and Philosophical Society of Manchester, January 2, 1838, by Prof. Ransome, of which Society I am a member, that he had kept water for months in an open vessel, and by an occasional addition of rain-water, and with the low evaporating points and fat

bordure towards the south, resembling much a long winding bay on the estuary of a large river, when the tide is out, and the shoals left dry. We descended to the shore by a pass more steep, rugged, and difficult, than is to be found among the Alps, and pitched our tent near the fine large fountain which bursts out upon a narrow terrace, still 400 ft. above the sea. The water of the fountain is beautifully transparent, but its temp. is 81° of Fahr. The whole descent below the fountain was apparently once terraced for gardens, and the ruins of a town are seen on the right. The whole slope is still covered with trees and shrubs of a more southern clime; among them we found the Oshor, the fruit of which corresponds best to the ancient descriptions of the Apples of Sodom. Nothing is needed but tillage to render this a most prolific spot; the soil is rich, the heat great, and water abundant. Of birds we saw many: indeed, at early dawn, the trees and rocks and air were full of the carols of the lark, the cheerful whistle of the quail, the call of the partridge, and the warbling of innumerable songsters; while birds of prey were soaring and screaming in front of the cliffs above." We are informed by an authority which we ought to credit above all others, that "Salt is good;" and it is only when it becomes like what chemists would call *caput mortuum*, that "It is neither fit for the land nor for the dunghill, but men cast it out." But perhaps some of your correspondents could say whether the "salt of the earth" literally means common salt or carbonate of soda.—*Peter Mackenzie.*

Quality of English grown Larch and Scotch Pine Timber.—Some time ago I made some observations in the *Gardeners' Chronicle* upon the quality of Larch timber from the red and pale-blossomed varieties. Last spring an intelligent friend of mine, a worker of timber, at my request marked some trees of each variety, had them felled, worked them up, and found that the variety with red blossoms produced the red Larch timber, by far superior in every respect to the timber from the pale-blossomed variety. Now, as this is a fact, and one of very great importance, it would be advisable for all persons entrusted with the thinning of Larch plantations to notice the colour of the blossoms and to mark the trees, so that those producing the pale blossoms may be taken out and the others reserved for timber. June is the best time to fell resinous trees for durability, my friend—an observing experienced man in such matters—says, just when the sap begins to be fluid, before the first buds and leaves are expanded, as there is more of the resinous fluid afloat, or at least it is more regularly dispersed in the wood. Perhaps some of the intelligent readers of the *Gardeners' Chronicle* will say whether this is the fact. As to quality of the decried home-grown Scotch Fir, there is a beam in a house near my residence which is known to have been in it nearly, if not quite, 100 years, quite sound yet; which Fir was not grown on a high situation, where the timber of the Scotch Fir is considered to be the best, but from a rich plain some miles off, where the owner resides. Were the proper training of our home-grown Pine timber properly understood, there can be no doubt but it would be equal to any foreign. This important subject is not attended to at the present day as it ought to be; but when the popular rage for new manures and agricultural improvement has had its day, this neglected subject may, perhaps, be taken up as a novelty and have its day also. In the meantime, neither the great landed proprietors nor the Government seem to be fully aware of the evils of delay.—*W. Billington.*

Italian Rye Grass.—In answer to the inquiry of your Correspondent "A." as to whether I have ever harvested a crop of Wheat, which immediately succeeded Italian Rye grass upon heavy land, I am enabled to state that, on a heavy loam upon clay subsoil, for several years I have grown Italian Rye-grass with Red Clover for mowing, and that the crops of Wheat which immediately succeeded were invariably regular and good; much better, indeed, than the same kind produced after summer fallow, before it was underdrained. It has frequently happened that in consequence of the failure of the seeds on small portions of the fields, on account of the heavy crops of the Barley sown with them, Italian Rye-grass was sown on such patches after harvest, and the Wheat was then sown there after Italian Rye-grass alone, and there has not been any perceptible difference in the crop of Wheat in those cases. Upon strong land, well under-drained, and in good condition, it is advisable to sow Beans, Peas, or Tares previous to Wheat upon lea pasture, and if such land be in high condition, clean and suitable for Oats, that crop might be taken after lea, and before Wheat; but in all cases it is advantageous to skim-plough the land on breaking up lea, and with such treatment and close drilling, though the subsequent crop may not require hoeing or much weeding, a full and productive crop of Wheat of good quality may be obtained from strong land after Italian Rye-grass.—*John Parkinson, Ley Fields, Newark, Notts.*

Miscellaneous.

Second Report of the Chowbent Farmers' Club. A. Hall, Honorary Secretary.

Pamphlets containing an expression of the opinions of practical men on farming subjects, which must always give works of this class a high character in the eyes of farmers, this tract records an instance in which the usefulness of science to the Agriculturist is apparent. The superiority of one sort of lime as manure over another, both of them being from quarries in the vicinity, was explained by an analysis of specimens undertaken at the instance of a neighbouring Farmers' Club. We extract the following notice of this matter:—

"Chemistry, having several specimens of limestone all made use of in burning lime for manure, one was found to consist of nearly pure carbonate of lime, while the others had a quantity of magnesia in combination, varying from two-fifths to nearly one half the limestone. When it is taken into consideration that magnesian lime is generally acknowledged to be injurious to vegetation, at least in the quantity usually applied to land, the importance of some knowledge of the composition of soils, and the means of ascertaining the difference of substances often used indiscriminately as manure, must be admitted, particularly so when to the casual observer no difference may be apparent.

"Opinions have varied respecting the effects of magnesian lime when applied in moderate quantities, probably from the different kinds of soil on which it has been tried; but all the writers to whom your Committee have had the opportunity of referring, agree in stating that an overdose of this substance will cause a temporary sterility. Dr. Ure says,—'The lime resulting from the calcination of magnesian limestone appears to have an injurious effect on vegetation, unless applied in quantities considerably less than common lime, when it is found to fertilize the soil. After two years its hurtful influence seems to become exhausted, even when used in undue quantity. Great quantities of it are annually brought from Sunderland to Scotland by the Ayrshire farmers, and employed beneficially as a manure in preference to other kinds of lime. It has been unfairly denounced by Mr. Tennent and Sir H. Davy as a sterilizer.'

"Geological writers affirm, that the magnesian limestone is often found beneath a fertile soil, generally of a light description; and this may well be the case, even though a quantity of the finer particles of the stone be blended with the soil; because the magnesia, as a carbonate in the limestone, is in an inactive or harmless state, but when the carbonic acid is expelled by heat the magnesia becomes caustic, and, in quantity, is injurious to vegetation. It is probable that a larger proportion of magnesian lime may be advantageously applied to one soil than another; and the committee are rather of opinion, though without any precise data to come to a positive conclusion, that the greater the quantity of vegetable matter in the soil, the less likely will the application of magnesian lime be to prove injurious. The Committee are rather inclined to go farther, and favour the opinion, that on peaty soils the magnesian lime would be found more fertilizing as a manure than any other kind."

Brief Remarks on some Subjects connected with the Choice of Wheat for Seed; interesting to Farmers, Corn-factors and Bakers. By Sir G. S. Mackenzie, Bart., F.R.SS. L. & E. Maclachlan, Stewart, and Co., Edin., pp. 30.

We have only time at present very shortly to notice this work. It is on a most important subject, and we shall next week direct the particular attention of our readers to it.

The Author shows that most of the external characters, from an examination of which millers are accustomed to estimate the value of samples of Wheat submitted to them, are unworthy of confidence; that they are as likely to mislead, as to guide one to a correct judgment; and that, in fact, the dealings between farmers and Corn-factors have hitherto partaken very much of the character of guess-work. This assertion is founded upon a great many facts and chemical analyses, which are detailed at considerable length, but as we shall refer to these next week, we leave them at present, merely saying that much light is thrown by them upon a subject which has been hitherto neglected, although, as the title of this pamphlet truly tells us, it is one most important and "interesting to farmers, Corn-factors and bakers."

Miscellaneous.

Effects of soaking Seeds in Chemical Solutions.—I steeped the seeds of the various specimens exhibited, in sulphate, nitrate, and muriate of ammonia, in nitrate of soda and potass, and in combinations of these, and in all cases the results were highly favourable. For example, seeds of Wheat steeped in sulphate of ammonia on the 5th of July had by the 10th of August, the last day of the show, tillered into nine, ten, and eleven stems of nearly equal vigour; while seeds of the same sample, unprepared, and sown at the same time, in the same soil, had not tillered into more than two, three, and four stems. I prepared the various mixtures from the above specified salts exactly neutralised, and then added from eight to twelve measures of water. The time of steeping varied from 50 to 94 hours, at a temperature of about 60 deg. Fahrenheit. I found, however, that Barley does not succeed so well if steeped beyond 60 hours. Rye-Grass and other gramineous seeds do with steeping from 16 to 20 hours, and Clovers from 8 to 10, but not more; for, being bi-lobate, they are apt to swell too much and burst. The very superior specimens of tall Oats, averaging 160 grains on each stem, and eight available stems from each seed, were prepared from sulphate of ammonia. The specimens of Barley were prepared from nitrate of ammonia; they had an average of 10 available stems, and each stem an average of 34 grains in the ear. The other specimens of Oats, which were next the most prolific, were from muriate of ammonia, and the preeminent specimens of Oats were from nitrates of soda and potash—strong, numerous in stems, (some having not less than 52), and not so tall as either the preparations from the sulphate or muriate of ammonia.—*Mr. Campbell, Transactions of the Highland Society.*

On Fattening Cattle with Different Kinds of Food.—The cattle were bought at Falkirk, on the 12th of October, and on the 24th were littled and put into separate yards, each of which had ample space and shelter from the weather, by scooped sheds for the several lots which were distributed among them; and conceiving that the object which the Agricultural Society had in view in offering this premium was to find out a substitute for Turnips, each lot of cattle had a mixture of food allowed them, with the exception of lot No. 1, which was altogether fed upon Turnips and Straw, and may on that account be denominated the trial lot; No. 2 had half the quantity or weight of Turnips which was allowed to No. 1, with 30 lbs. of linseed oil-cake, as a substitute for the remainder of the Turnips; No. 3 had the same weight of Turnips which was given to No. 2, and half-ground Corn in the place of the oil-cakes; the fourth lot got offal from a grain whisky distillery, and a portion of ground Beans, which was mixed into their draff every morning. By following out this arrangement we have ascertained the quantity of Turnips saved, the value of the Turnips in feeding by themselves, combined with the other substances, and their value as an auxiliary feeding when used with those richer substances, which, without some coarser food, will neither be an economical nor a beneficial food for cattle. All the lots had fresh straw given to them daily, which was not weighed, and below is a state of the food consumed and the expense incurred in the fattening of each lot:—

LOT NO. 1—FED ON TURNIPS.

		£	s.	d.
Oct. 12,	To price of five cattle	245	0	0
24,	— 10 days keep of ditto on Turnips and Straw, at 8d.	8	6	8
Jan. 1,	To 84 tons white globe Turnips, at 4l. 4d. per ton, since 24th October till this date, being 3cwt. per day	34	3	4
April 7,	To 38 tons, 16 cwt. ruta bags, at 12s. 6d. per ton, since 1st January till this date, being 8 cwt. per day	24	7	6
		£306	16	6

At this date the Judges appointed by the Committee of Management, inspected the cattle, and reported their value to be 420l.

June 7,	To 21 tons, 1 cwt. ruta bags since 7th April till this date, at 12s. 6d.	13	0	6
		£127	3	6

The average expense of the keep of this lot is about 6s. 2d. per week each beast.

LOT NO. 2—FED ON TURNIPS AND OIL-CAKE.

		£	s.	d.
Oct. 12,	To price of five cattle	245	0	0
24,	— 10 days keep on Turnips and Straw, at 8d.	0	6	8
Jan. 1,	To 17 tons white globe Turnips, at 8s. 4d.	7	1	8
April 7,	To 19 tons 8 cwt. ruta bags, at 12s. 6d.	13	0	0
	— 1 ton 18 cwt foreign linseed oil-cake, at 7l. 15s. per ton, since 16th Nov. till this date, being 30lbs per day	14	14	6
		£279	4	4

Estimated value at this date, 32l. 10s.

June 7,	To 10 tons 14½ cwt. ruta bags, at 12s. 6d.	6	14	1
	— 15 cwt. 28 lbs. linseed cakes, at 8l.	5	10	0
		£103	19	1

The average expense of the keep of this lot is about 5s. 6d. per week each beast.

LOT NO. 3—FED ON TURNIPS AND BROWN CORN.

		£	s.	d.
Oct. 12,	To price of five cattle	235	0	0
24,	— 10 days keep on Turnips and Straw, at 8d.	0	6	8
	— 17 tons white globe Turnips, at 8s. 4d.	7	1	8
April 7,	To 19 tons 8 cwt. ruta bags, at 12s. 6d.	13	0	0
	— 1 ton 14 cwt. 90 lbs. of Bean meal, or 62 bushels ground Beans, weighing 32 lbs. per bushel, at 5s.	15	15	0
	To 9 bushels bruised Oats, at 2s. 6d.	1	11	3
		£271	17	6

Estimated value at this date, 77l.

June 14,	To 10 tons 14½ cwt. ruta bags, at 12s. 6d.	6	14	1
	— 1 ton 9 cwt. 180 lbs. Bean meal, or 84 bushels ground Beans, weighing 32 lbs. per bushel at 5s.	15	10	0
		£112	1	6

The average expense of the keep of this lot is about 6s. 7d. per week each beast.

This lot had latterly the rough seed of Oatmeal, at 1½d. per bushel, as a mixture to the Bean meal, which are not charged, being worth the price as manure.

LOT NO. 4—FED ON DISTILLERY GRAINS AND GROUND BEANS.

		£	s.	d.
Oct. 12,	To price of five cattle	255	0	0
24,	— 10 days keep on Turnips and Straw, at 8d.	0	6	8
Nov. 7,	— 2 tons 3 cwt white globe Turnips, at 8s 4d.	1	7	1
April 7,	— 72 quarters draff, at 4s. 6d.	16	4	0
	— 40 puncheons dreg, at 3s. 6d.	7	10	0
	— 1 ton 14 cwt. 62 lb. Bean meal, or 62 bushels ground Beans, weighing 62 lbs. per bushel, at 5s.	15	10	0
		£295	17	9

Estimated value at this date, 81l. 10s.

June 14,	To 27½ quarters draff, at 4s. 6d.	3	8	9
	— 22 puncheons dreg, at 3s 6d.	3	10	0
	— 19 cwt. 104 lbs. Bean meal, or 86 bushels ground Beans, weighing 62 lbs. per bushel, at 5s.	9	9	6
		£316	15	3

The average expense of the keep of this lot, is about 7s. 6d. per week each beast.

At the commencement of these experiments, No. 1, whose feeding was destined to be Turnips alone, that being the kind of food which they were formerly accustomed to, made a more immediate improvement than the cattle of the other lots. Upon the whole, it is evident by these experiments that feeding with Turnips *as an auxiliary* has been the most advantageous mode of using them, for it is apparent that if the cattle of lot No. 1 had only been allowed half the quantity of Turnips which they consumed, and had got oil-cake in lieu of the other half as was given to lot No. 2, the expense of their keeping would have been lessened 4l. 15s., and from superior quality their value would have been increased 10l., making together 14l. 15s.; therefore, by bestowing the remainder of the Turnips, with the addition of oil-cakes, upon other five cattle, the profit upon the Turnips eaten by lot No. 1 would have been 29l. 5s. additional to what it has been. These experiments were carried on for two months after the valuation was made at the show in April; as from an over supply in the market, caused by a scarcity of Turnips, the cattle would not them have paid for their keep; but by

continuing till June I have been simply remunerated for all my outlay and trouble, without taking into account the great advantage of the additional and enriched manure of twenty cattle fattening upon the farm, where ten only could have been kept had Turnips alone been used for that purpose; and to any person at all acquainted with Agriculture it must be evident that one cart load of manure made by cattle thus fed will be at least equal to two if the cattle had got only straw and water. The above experiments, which are corroborated by those conducted last season by Messrs. Andrew Howdon and Alexander Brodie, junior, tend to show that the winter feeding of cattle is more capable of successful extension by those who have a sufficiency of straw, but have not such an abundance of Turnips as to be able to make all their straw into manure by cattle upon full feeding, than was formerly imagined.—*Experiments by Mr Brodie, of Abbey Mains, Haddington*, 1856-7.

Roots of Plants.—In loamy or sandy soils, the roots of trees have been found to penetrate to the depth of 10 or 12 feet; and the roots of the Canada Thistle have been traced 6 or 7 feet below the surface. Wheat, if planted in a mellow rich soil, will strike its roots 3 feet downwards, and elongate much further horizontally. The roots of Oats have been discovered at 18 inches from the stem, and the long thread like roots of grass extend still further. The roots of an Onion are so white, that in black mould they can be readily traced, and in a trenched or spaded soil they have been followed to the depth of two feet. The Potato throws out roots to the distance of 15 or 20 inches; and the tap-rooted plants, Turnips, Beets, Carrots, &c., independent of perpendicular roots, spread their fibres to a distance which equals if it does not exceed the Potato. It is perfectly absurd to expect to succeed with roots of this class, unless the ground is so mellow as to allow them to penetrate and grow freely.—*Chatham Journal.*

Manuring and Steeping of Seeds.—The quantity of inorganic matter contained in the grain of Wheat, Oats, Barley, &c., is comparatively small. But, though small in quantity, this inorganic matter is absolutely essential to the perfect condition of the seed, and to the healthy growth of the plant that springs from it. When seeds are steeped in water, they swell and increase in bulk. They absorb a portion of the water and of any saline substances it may hold in solution. Now, if the small quantity of saline or inorganic matter which exists in seeds does really promote their growth, may not a larger quantity promote it more? May not the growth be more luxuriant if the seed be steeped in water containing saline substances in solution, and be thus made to absorb an additional proportion? It does not appear unreasonable to suppose that a bushel and a half of seed-Wheat may be made to absorb a pound of saline matter. This appears, indeed, to be only a very small quantity, and yet, if absorbed, it would add one half more to that which the seed naturally contains. We cannot pronounce beforehand, with absolute certainty, that by this absorption the growth of the seed would be greatly promoted, though both theory and practice concur in rendering it probable. Thus the experiments of Bickes—whose mode of preparing seeds appears to be a simple steeping in saline solutions—appear decisive in favour of the opinion, that such artificial additions to the saline matter of these do really, in some cases at least, greatly promote the growth of the seeds, and increase the luxuriance and produce of the after crops. Further, we know that some seeds germinate much more readily and certainly than others. We know, also, that the proportion of inorganic matter, or of ash they leave when burned, varies in different samples of seeds of the same kind. That contained by Wheat, for example, is sometimes 2½, sometimes 1½, and sometimes nearly 2 per cent. of its weight. Can this difference in the growth of seed and the difference in the proportion of saline matter have any connection with each other? Do some germinate feebly, do others fail entirely, because they contain too small a proportion of the usual saline constituents of the seed? Would they germinate better if more were by some means given to the seed? The same experiments of Bickes, upon the effect of steeping, seem almost to answer these questions in the affirmative.—*Professor Johnston, in the Journal of Agriculture.*

Notices to Correspondents.

Our Correspondents will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

Communications from the following Correspondents are in type, and are only waiting till room can be found for them—*T. R., Martin Doyle, Fairlaik Clay, M. B. G.*, and *J. Hirets*.

Nitric and Muriatic Acid.—*A Nottinghamshire Subscriber.*—Digest the bones in one half their weight of muriatic acid diluted with an equal weight of water. The application of heat to facilitate the action will not injure it as a manure.

Nitric and Sulphuric Acid.—*A Subscriber's* request has been forwarded to Mr. Lawes.

Experiments on Exciting Farmers.—*An Inquirer.*—It is difficult to discuss such a subject as that you refer to in a manner free from such *party spirit* as must not be allowed in our columns. If, however, we can obtain a true and detailed statement in answer to your question, we shall publish it for you.

Cultivation of Turnips for Seed.—*R. W.* will find information on this subject in p. 16, of the English Agricultural Society's Journal, vol. i. The extract is too long to insert. We believe Smith's Turnip Cutter is as efficient and inexpensive as any of the class.

Books for Land and Manure.—*Agricola.*—Your first letter must have miscarried. We have only received your second; and, in answer to it, we know of no better drill than those made by Mr. Mowbray, of Grantham, Lincolnshire, which manure, destroy them to sow all kinds of seed with manure. Further must be said, but perseverance in destroying their subsequent stinging nettles by cutting out their roots.

Early Potatoes.—*J. M'L., Hillsborough.*—Sibbe's Early, and Prince's Early, are two early varieties suitable for field culture. The Gold-finder is also a good sort.

Gardeners' Chronicle and Agricultural Gazette.—*Upsilon.*—Thanks for your letter. We do not differ much, in our opinion on the subject of it.

Gold of Pleasure.—*E. S. N.*—We have never cultivated this plant, but will gather up for you what we can about it from others.

Grass Seeds.—*J. R.*—In some seasons the Barley is a protection to the young Clovers and Grasses sown with it, and it is very rarely that the injury which it may in some cases may be done by it, is greater than the value of the crop fully compensates for. When the winter is not generally severe it is a good plan to feed young Clover off in Autumn, but this practice is said to be injurious where it is succeeded by sharp frost.

How to Destroy Moss in Grass-land.—*M.*—Measure the land well in autumn with a good dusting of rich, well-made farmyard dung, and feed the Grass off with sheep. This is better than lime. You will see a reason given in "Sprengel on Inorganic Manures, No. III.," *Agricultural Gazette*, why you should mix lime with earth previously to applying it on land which is not very rich in vegetable matter.

Jamaica Agriculture.—*A Jamaica Planter.*—Will you allow us to look at these papers? We should not like to insert articles having no bearing upon *British* farming.

Manures.—*J. B. H.*—It is dangerous to apply guano immediately to a crop. It is better to mix it with ashes or earth before it is spread over Grass. If, however, the labour of carting comes in your way, try sowing it broadcast, as you propose, during wet weather. We do not understand how, in the case of animals chewing the cud, Beans could pass through them whole, especially when they had been previously soaked.—*Trifolii.*—Nothing beats good farmyard dung. Guano is next best, applied at the rate of 3 cwt per acre. Mix it well with soil before applying it.

Manuring Grass Land.—*Medicus Ashburtonienses.*—You had better mix the contents of the pits you allude to with fresh mould, in order to give the matter a form in which you can apply it to your land. It may be applied after the rate of 20 or 30 bushels an acre. The Guano must either be mixed in the same way before spreading over your grass land, or it must be applied during wet weather, 2 cwt. an acre is a sufficient quantity.

Ringing Pigs.—*F.*—Your question, and all others having reference to veterinary art, will be answered shortly.

Salt and Lime.—*A Subscriber.*—Mix 1, or at most 2 cwt., of salt with the quantity of lime you intend to put on an acre, and spread the lime in the usual way. (See "Johnson on Fertilisers.")

We do not know personally of any case in which it has been tried, although there are many published testimonies to its value as manure.

Sawdust as Manure.—*K. B.*—It must either be mixed with farmyard manure, and so used as a compost, or, what would be better where it is produced in such large quantities, it must be burnt, and its ashes used as manure. It would do very well as manure if soaked with urine from the tank.

Sheep-feeding Sheep.—*A Subscriber.*—We have at this moment 200 sheep which have been treated, as described in our Leader No 3, *Agricultural Gazette*, since October last, whose feet have been, and are now perfectly sound. We have others which have become lame since they were brought under shelter, but probably this is owing to a previous tendency to foot-rot. It is a bad plan to tie the sheep up all together, and the manure should be removed from under them periodically—say once a fortnight.

Soils.—*J. Marshall.*—If you are not desirous of an *immediate* answer, we shall endeavour to give you one, perhaps by next *Gazette*, but if you are, you must put the matter in the hands of a Chemist, who will analyse the specimens for you.

Stephens' Book of the Farm.—*A Subscriber.*—The prolixity of certain periodical works, this among the number, is certainly blameworthy. You will see our opinion of it in No. 3, *Agricultural Gazette*.

Swedes for Seed.—*C. W. W.*—You had better break off the sprouts that are appearing now, for if you do not, even though the frost should spare them, they will come to blossom at an unseasonable time.

*** As usual many communications have been received too late for answering this week.

Markets.

SMITHFIELD, Monday, Jan. 26.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 10 to 4s 2	Best Downs & Half-breds	4s 0 to 4s 4
Best Short Horns	3 8 3 10	Best Long woolled	3 8 4 0
Second quality Beasts	3 2 3 6	Prime and second quality	3 4 3 8
Calves	4 4 4 4	Pigs	3 4 4 4

Numbers.—Beasts, 2715; Sheep, 27,120; Calves, 78; Pigs, 290.

Although the numbers are to-day considerably less than last Monday, we cannot observe any improvement in the trade. The demand is very limited—partly accounted for by the large arrivals of packed meat in the dead markets the weather being, on the whole, pretty favourable for it, and being sold at a cheaper rate, the butchers have bought more largely dead, and, consequently, less alive. There is no quotable difference in Beef. An Half bred sheep from Norfolk and Downs from the Western Counties, are now more plentiful, these descriptions of meat are lower. The Longwools keep about the same as of late, the sale of them being much helped by the advance in skins. Good Calves are again dearer, some few superior have realised 4s 6d per 8lbs. Pigs are a heavy trade at the same prices as our last.

FRIDAY, Jan. 26.

The supply to day is small, but fully adequate to the demand. There have been very large arrivals of dead meat from Holland since Monday, which at this time of year has great effect on our market. Beef is fully 2d. per 8lbs lower than on Monday. Mutton keeps about the same price. Good Veal is still dear. There is rather a larger supply of Calves, but many are of inferior quality; the best are still worth full 4s 4d, and something very choice may be quoted at 4s 6d per 8lbs. Pork trade is rather more cheerful, making from 3s 8d to 4s 0d.

Numbers.—Beasts, 680; Sheep, 8180, Calves, 148, Pigs, 240.

61, West Smithfield.

POTATOES, Jan. 22.

Southwark Waterside.—Since our last Report there has been some considerable arrivals, both from Yorkshire and Scotland; and, notwithstanding the former part of the week set in cold and frosty, it was only of short duration, and again became mild and fine. The demand was languid at former quotations, yet, in consequence of the supply from other districts having been very limited, an advance on some of the best samples was asked, but the dealers had no inclination to pay them at the advanced prices. The above some of the quotations may be considered nominal, and especially 70s. for Devonshire and Cornwall Reds.

York Reds	60s to 80s	Kent and Essex Whites	55s
Perth	80	Kidneys	60
Early Devons	80 90	Whitnash Kidneys	70 75
Cornwall	65 70	White and Blues	60 65

Rapeseed and Lin.

WOOL.—British, Friday, Jan. 26.

A case many sales have been effected in our English Wool Market during the past week at rather improved rates. Although our reports from the manufacturing districts intimate by no means a good trade being done, they state that the prices of manufactured articles have not advanced in equal proportion with that of the raw material.

	per lb		per lb
Leicestershire Wethers	1s 2d to 1s 3d	Southdown Shearlings	1s 4d to 1s 6d
Ewes	1 1	Ewes	1 1 2d
Southdown Wether Hogs	1 4		

Mincing Lane, Friday, January 26.—The arrivals of Wheat since Monday have been moderate, but the Trade on Wednesday and this morning has been dull, and part of the Kent stands are not cleared. Foreign remains very limited inquiry, but holders continue firm in their demands; we have occasional buyers for floating cargoes, and Dantzig 57s. on board; Polish Odessa is generally held at 55s. to 56s., and Dantzig 57s. to 58s. and 62s. according to quality.—Fine Malting Barley finds buyers at our quotations of Monday last, but inferior qualities are the turn cheaper.—In Beans and Peas we observe no alteration.—The supply of Oats is considerable, and the sale difficult at late prices.

Rinscoed and Lay.

COVENT GARDEN, Jan. 26.—In consequence of the continued fine weather the market has been well supplied during the week, but trade still remains dull. Fine Apples are getting scarcer; they are selling at nearly the same prices as last week. Hothouse Grapes are very scarce, but Portugals are sufficient for the demand. Among Apples we noticed the Golden Pippin, and good specimens of Blenheim Orange. Samples of Beurré Rance and Easter Beurré Pears, in addition to those mentioned in a previous report, have been brought to the market during the week. A few Sanguine Oranges have made their appearance in the market. Lemons are plentiful, and Filberts are sufficient for the demand. Vegetables generally are abundant. Cabbages are good and plentiful. Brussels Sprouts and Greens are abundant, but Broccoli is rather scarce. Seakale and Rhubarb, of good quality, are sufficient to meet the demand. Parsley is offered at the same prices as last week. Asparagus continues scarce. Endive is plentiful, and Shallots are equal to the demand. Celery is rather inferior in quality. Cut Flowers chiefly consist of Lilies gracilis and hyemalis, Bignonia venusta, Euphorbia jacquiniflora, Azalea indica alba and Smithii, Poinsettia pulcherrima, Pelargoniums, Primulas, Acacias, Camellias, Chrysanthemums, and Roses.

Repository of Industrial Manures, 49 & 50 Mark Lane.

DANE GROVE NURSERY, STOWMARKET, SUFFOLK.

SAMUEL GERLING, ENGLISH AND FOREIGN DAHLIA dealer, submits the following choice and DARLING DAHLIAS to his numerous Friends for 1844, some of which can be had early in May; they are all faithfully described, and early orders are respectfully solicited, as the stock of some of them is very limited. General Catalogues of DAHLIAS, GERANIUMS, PANSIES, FUCHSIAS, and VERBENAS, can shortly be had, on prepaid application

BEAUTY OF SUFFOLK (Dane's) —Bronzy purple, of superior form and excellent habit; a constant and extra second rate show-flower; seedling raised at Ipswich and Stowmarket. Height 4 feet.—Price 7s 6d.

DERMONDERY BEE (Faberon's).—A crimson purple, of excellent form and fine general habit, well cupped alike petals; would well crown one of the best Self Dahlias in cultivation.—4 ft.—10s 6d.

MODEL (Bowen's).—Dark purple, of first rate form, has taken first prizes at the Metropolitan and other shows, and pronounced a first-class flower 4 ft.—10s 6d.

NOMPAREIL (Paceton's).—Ruby scarlet, of first rate form, habit excellent, free bloomer; pronounced by the Horticultural Society of London, and at the Slough exhibition, to be a first-class flower The stock of this beautiful Dahlia is small, and unless it breaks well will be held in another year No allowance on this variety unless six plants are ordered Blenny's opinion of this Dahlia is, that well grown it will be a prizeman. 4 ft.—10s 6d.

ORANGE PERFECTION (Bowen's).—Of good form and habit, an extra second-rate show-flower, rather low in the centre, but sometimes well up, when it will beat all the orange class 4 to 5 ft.—7s 6d

RED ROVER (Gerling's).—Of good general properties and extra fine habit; colour fine red, and useful for showing. 4 to 5 ft.—7s 6d

TALMA (Gerling's) —Purplish rose of superior form and habit, little short of first-rate; rising centre and very constant 4 ft.—7s 6d.

SIR JOHN STEWART RICHARDSON (Union, in which S G has a share), which is one of the most popular Dahlias of the season. No allowance on this variety unless 12 plants are ordered 4 ft.—10s 6d

FANCY DAHLIAS.

CORNELIA (Gerling's).—Purple, tipped with white; of good habit and very distinct. 4 ft.—5s

GARLAND (Gerling's) —With three colours—crimson, sulphur, and brown tip; of good form and habit 3 ft.—5s

MADAME MIELLEZ (Gerling's).—Rose-lilac, tipped or striped with white, a distinct variety, of good habit 3 to 4 ft.—5s

MADAME DE BERGHE (Gerling's).—White edged with pink a distinct and beautiful variety. 3 ft.—5s.

MADAME CHAUVIERE (Gerling's) —Light crimson tipped with pure white, very constant, good shape, and one of the finest border Dahlias in cultivation 4 ft.—5s

VILLAGE MAID (Gerling's) —Colours white and purple distinctly and beautifully tipped; good habit and superior border variety 3 to 4 ft.—5s —Stowmarket, Jan 19 1844

THE BRITISH QUEEN AND PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above two new Varieties, the merits of which are thus noticed in the *Gardeners Chronicle*, "THE BRITISH QUEEN on light soils, is the best of all kinds, and will drive Knight's Tall Marrow out of the garden" "THE PRINCE ALBERT, which has been cultivated in the Garden of the Horticultural Society during the season, produced Peas fit for the table *ten days earlier* than any other variety sown at the same time" Both varieties may be had in packages at 2s 6d each, at W J C 's wholesale Establishment, Newcross or the Bedford Conservatory Covent Garden

WILLING'S EARLY GROTTO PEA

J AND S SHILLING have succeeded in raising the above PEA, the Early Frame Pea, impregnated with the Grotto or Oyster Marrow, which they, with confidence, recommend to the Public generally, being quite as early, and nearly double the size of any other Pea in cultivation Quite hardy will stand the winter well, and a good bearer, the pod large and long They would particularly recommend it to the attention of Market Gardeners Price 2s per quart, 10s per gallon 17s 6d per peck; 30s per half-bushel; 2l 10s per bushel Agents:—Messrs. FIELD and CHILD, 119 Lower Thames street, London Messrs W. and J NORRIS, 152, Fleet street; Mr KERNAN, 4 Great Russell-street, Covent Garden; Messrs HOGGE and McMULLEN, 61 Leadenhall street; Messrs GRAY, ADAMS, and HOGG, Kensington; Mr. T. D WATKINSON, Market place, Manchester —Northwarnborough Nursery, near Odiham Hants

TO FLORISTS, NURSERYMEN, &c

AUSTIN & SHELLEY have now a Quantity of GARDEN ORNAMENTS, which have been discoloured by exposure to the London atmosphere, and which they are therefore desirous of selling at a considerable reduction.—New Road, Regent's Park.

TO CULTIVATORS OF PEARS.

T. RIVERS, Jun, begs to announce that his Descriptive Catalogue of Pears, with some directions for their Culture, as root-pruned Pyramidal, Conical, and Quenouille trees of which wood-cuts are given, is now ready for delivery, to which is appended a Supplement to Catalogue of Fruits The Pamphlet will be sent, post-free, for 1s 6d, on receipt of a paid application. Sold also by Messrs LONGMAN and Co, and at 4, Great Russell-street, Covent Garden. The Catalogue of Pears is printed separately, and will be sent to applicants on receipt of a two penny stamp.—Sawbridgeworth, Herts, Jan 4, 1844

SEED TRADE—NO MONOPOLY.

J. C. WAITE, WHOLESALE SEEDSMAN, 1 & 2, Eyre street hill, Hatton Garden, London, most respectfully solicits the attention of the Country Trade to his prices of Seeds recently advertised in the *Chronicle*, and to remind them that everything is quoted very much below the *London Agreed List* All articles sold at his Establishment are of superior Quality, and genuine Stock—Bills to be had on application.

WARNER AND WARNER, SEEDSMEN, 22, Cornhill, London, beg respectfully to refer their Friends to the *Gardeners' Chronicle* for January, for their Advertisement of New and Select VEGETABLE and FLOWER SEEDS

WARWICKSHIRE ASSOCIATION FOR THE PROTECTION OF AGRICULTURE.

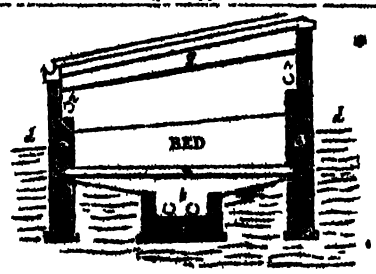
AT a numerous MEETING, convened by Requisition, and held by adjournment (from the WARWICK ARMS HOTEL) at the COUNTY HALL, WARWICK, on WEDNESDAY, JANUARY the 24th, 1844 the Right Hon LORD BROOKE in the chair, the following Resolutions were unanimously carried:

1st —Proposed by E B GRANVILLE, Esq, and seconded by G N NEWDEGATE, Esq, M.P.—"That it is the firm and decided conviction of this Meeting that a Repeal of the Corn Laws would be highly prejudicial, not only to British Agriculture, but to the nation at large, would impolitically diminish the income of the Land-owners, unjustifiably annihilate the capital of the Tenant Farmers, cruelly reduce the wages of the labourers below the means of sustenance, and consequently impair, if not destroy, Home Consumption, that great source of demand for the labour and industry of the people in all their branches"

2d —Proposed by the Rev J C ROBBINS, and seconded by E B KING, Esq —"That all efforts to effect a *violation of the protective principle*, under existing circumstances, not only as regards Agriculture, but our National Industry in general, ought to be vigorously opposed."

3rd —Proposed by Sir J MORDAUNT, Bart, M P, and seconded by Mr C LUCY,—"That the doctrines of the Anti Corn-Law League, tending to produce jealousy and devil feeling amongst the several classes of the community, and having ulterior mischievous objects in view, are dangerous to the prosperity and peace of the country, and ought to be exposed and resisted"

4th —Proposed by Mr CHAPMAN, and seconded by Mr WARRINGTON,—"That the Committee of the Association be requested to correspond with other Societies, formed for a similar purpose, and to adopt such measures as to them shall seem expedient, in effectually exposing and vigorously arresting the progress of the pernicious principles and objects of the Anti Corn-Law League



5th —Proposed by Mr HOUGHTON, and seconded by Mr LISTER, —"That the Warwickshire Association having been mainly supported by the Farmers, it is recommended that all classes dependent on the productive industry of the county be invited to co-operate, and that in furtherance of this purpose, donations be received by the Secretaries from all persons disposed to forward the object of this Meeting"

6th —Proposed by H C WISE, Esq, and seconded by Mr HEMMING, —"That the foregoing Resolutions be printed, circulated, and advertised in such manner as the Committee may approve"

The noble Lord having left the chair a vote of thanks to him was proposed by Sir JOHN MORDAUNT, Bart M P, seconded and carried by acclamation, for his Lordship's able and impartial conduct as President of the Meeting

READLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO, 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose These tanks which are ornamental in appearance can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of iron will be found cheaper than of any other material Mr. READLE of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S and Co

J WEEKS & Co., ARCHITECTS, HORTICULTURAL BUILDERS, and HOT-WATER APPARATUS MANUFACTURERS, Gloucester place, Kingsland road, Chelsea.

BURRIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon they have put up one at the Horticultural Gardens, where E and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of iron Tank, which combines the qualities of the round pipe and Hotwater tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Orchards, Euphyte-houses, Melonhills, &c. The arrangements is such that any gentleman or gardener may have the Whole Constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 150, Fleet-street. A Prospectus may be had detailing the prices, &c.

GUANO ON SALE BY THE IMPORTERS, JOHN GIBBS & SON, Wellington Chambers, London Bridge, Borough.

CHEAP FUEL FOR HOTHOUSES AND STOVES.

—Coke, the same as used by the Horticultural Society, to be had in large quantities at very reduced prices, at the Phœnix Gas Works, Bankside, or Greenwich

GENUINE PERUVIAN & BOLIVIAN GUANO ON SALE, BY THE IMPORTERS, ANTONY GIBBS AND SONS, LONDON; GIBBS, BRIGHT, AND CO, LIVERPOOL AND BRISTOL, 47, Lime-st., Jan 25, 1844

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine as imported.—Apply to Cornewall, Powell, and Payne, London; Edwards Dawson, and Co., Liverpool; or William J Myers and Co, Liverpool, the Importers

POTTER'S GUANO.—Sir Robert Peel, the Earl of Ellesmere, and others, have used POTTER'S MANURE with the greatest success on almost every kind of crop and soil. Testimonials may be obtained by application, per post, at the Works, 28, Upper Fore-street, Lambeth, or of any of Mr. Potter's agents.—See also the Advertisement in this Paper of the 6th Jan., containing Copies of the Testimonials referred to

GUANO, PERUVIAN, &c —The above Manures, also Potter's Guano, Nitrate of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with synopsis of mode of use, on application to MARK FOTHERGILL, 40, Upper Thames-street, London

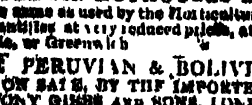
GUANO.—The Subscribers will bring in a cargo this MANURE to Berwick-upon-Tweed, in all February and March, direct from Valparaiso.

Haddington, Jan 22 1844, BAIRD & Sons.

Note —As this will be one of the *very few* cargoes from the Pacific, whose charterparties will admit of their discharging on this coast, BAIRD and SON would recommend intending purchasers to apply for what they may require as early as possible.

THE CURATE of the LONDON MANURE COMPANY, at per Ton It is with the greatest satisfaction, after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By producing a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops The Curate may be sown broadcast, or which is preferable, by the drill, at the rate of from two to three acres, and it is desirable it should not be placed more than two inches below the surface As a top-dressing for Wheat the Curate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and testimonials will be forwarded on application. Genuine Peruvian Guano, Phosphate and Sulphate of Ammonia, Gypsum and every other artificial Manure

EDWARD PURKIS, Secretary, 40, New Bridge Street.



GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c, impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it

Noblemen, Gentlemen, and Gardeners will, by using this composition have the only effectual protection for their Fruit from during the blooming season it is a certain defence from frost, sleet, wind, and blight; its transparency admits the grateful beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using

Sold in Bottles, with directions for use, pints, 2s 6d, quarts, 4s 6d each One pint is sufficient to coat four Frames twice over, each frame to be 6ft. by 3ft 3in., or thereabouts Prepared by GEORGE WHITNEY, Chemist, Shrewsbury Seedsmen, Florists, and Merchants supplied by Mr W BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents —Messrs. BUTLER and MACKLEY, Covent Garden, where a sample of prepared calico may be seen, Mr WATERHOUSE, Market place, Manchester, PACE and SON, Southampton; T and C WHALLEY, Nurserymen, Liverpool

Agents wanted for London and the country

BY HER MAJESTY'S ROYAL LETTERS PATENT.

I C F NELSON, Actuary.

CLOSE OF HOLIDAYS.

NOW THAT THE SEASON of Annual Festivity is about to terminate, and the respective Boarding Schools be reinstated by the busy throng of useful aspirants, the personal comfort and attractions of whom become naturally associated with friends and relatives of great solicitude, ROWLAND'S MACASSAR OIL, for accelerating the growth, and for preserving and beautifying the hair; ROWLAND'S KALYDOR, for preserving the skin and complexion, and removing cutaneous eruptions; and ROWLANDS ODONTO for beautifying the Teeth and preserving the gums, are unanimously considered indispensable in the requisite accomplishments of the fashionable Reputation)

The August Patronage conceded by our Gracious Queen, and the several Sovereigns of Europe, together with the Beauties which adorn the circles of Princely and Regal Magnificence and the confirmation by experience of the infallible efficacy of *these grateful preserving Specifics*, have characterised them with perfection and given them a celebrity unparalleled.

NOTICE —It is necessary on purchasing either article to see that the word "ROWLANDS" is on the Wrapper. For the Protection of the Public from fraud and imposition, the Honourable Commissioners of Her Majesty's Stamps have authorised the Proprietors to have their names engraved on the Government Stamp, thus —"A. ROWLAND and SON, 20, Hatton-garden," which is affixed to the Kalydor and Odonto. Be sure to ask for "ROWLANDS'S" Articles

Sold by the Proprietors and by all Chemists and Perfumers.

*** All others are FRAUDULENT COUNTERFEITS!!

GEOLOGY.—PROFESSOR WEBSTER, F.G.S., will commence his Lectures on Monday, 5th February. The Course will consist of 30 Lectures, and will be divided into three parts.

1.—The description of such simple minerals as enter essentially into the composition of rocks.

2.—Geology, properly so called, or the characters and superposition of the strata composing the crust of the globe, together with an account of the various phenomena exhibited by them.

3.—The application of the above subjects to the useful arts.

Lectures on Monday, Wednesday, and Friday, at a quarter past 12 o'clock. Fee 3*l*. The course is open to Gentlemen who do not attend any other class in the College.

P. E. Carey, Dean of the Faculty of Arts and Laws.
Charles C. Atkinson, Secretary to the Council.

University College, London, January 26, 1844.

CAMDEN CLUB, now forming at No. 12, Waterloo-place.—These premises so desirably situate, and expressly fitted up for a Club-house, with all the appointments ready for immediate occupation, have been obtained for the New Club.

TERMS OF ADMISSION.

Town Members' entrance . £10 10 0 Annual . £7 7 0
Country Members' entrance 5 5 0 Annual . 5 5 0

It is proposed to introduce a new principle into the constitution of the Club with regard to Town Members, by which a Member retiring shall have a rateable proportion of his entrance fee returned to him, according to the number of years he may have been a Member.

Prospectus containing full particulars of this new regulation may be had of the Secretary, at No. 12, Waterloo-place, where the Provisional Committee meet daily to receive applications from gentlemen desirous of becoming Members.

London, February 1, 1844.

THE LATE Mr. LOUDON.—A Public Meeting of the Friends of the late Mr. Loudon will be held in the large room of the Horticultural Society's Establishment, Regent-street, London, on Saturday, Feb. 17, at Two o'clock precisely, to consider the best means of extricating his Widow and Daughter from the difficulties into which they are placed by Mr. Loudon's sudden death.

It is hoped that noblemen and gentlemen who patronise Horticulture, and also all Gardeners and Nurserymen who are within a reasonable distance, will attend.

DEATH OF Mr. LOUDON.—The following Subscribers to the Works of the late Mr. Loudon have been obtained since the publication of the Address in the *Gardeners' Chronicle* of Saturday last.

ARBORETUM BRITANNICUM.—16*l*.

C. Wentworth Dilke, Esq.

Miss Horrocks, Dunchattan; works to the value of 2*l*. 10*s*.

ORANGE AND LEMON TREES, from 8*s*. to 25*s*.

DOUBLE ITALIAN TUBEROSE ROOTS, 3*s*. per dozen.—R. Hall begs to advise the arrival of his Annual Importation of the above-named Trees and Bulbs, which are this year remarkably fine, at his Foreign Warehouse, 52, South Audley-street, Grosvenor-square—facing the Chapel.

DWARF CHERRIES GRAFTED ON THE PRUNUS MAHALEB, OR PERFUMED CHERRY.

T. RIVERS, Jun., begs to offer the following sorts of CHERRIES, grafted on the above Stock, Root-pruned, and admirably adapted for potting, for forcing, or for forming Dwarf prolific Trees, to be protected by nets, 2*s*. 6*d*. each:—

Arch, or Holman's Duke
May Duke
Royal Duke
Late Duke
Biggarens
Black Eagle
Belle de Choisy
Elton
Early Amber Heart (Rivers's)
Florence
Knight's Early Black
Imperial Morello
Black Tartarian
Tradescant's Black
Waterloo
Werder's Black Heart.

The following Ornamental Standard Trees for Lawns are also offered:—

	each.		each.
American Weeping Willow, 8ft.	*s. d.* 5 6	Robinia macrophylla, or grandiflora, 6ft.	*s. d.* 3 6
*Cytisus elongatus (pendulous), 5ft.	2 6	*Yellow Broom, 5ft.	2 6
*Cytisus purpureus(do.), 5ft	2 6	Double Dwarf Almond, 4ft. to 5ft.	2 6
*Cytisus purpureus, double alba, 5ft.	2 6	Siberian Almond, 4ft. to 5ft.	2 6
*Cytisus nigricans, 5ft.	2 6	White-flowering Dwarf Almond, 4ft. to 5ft.	2 6
*Cytisus falcatus, 5ft.	2 6	Dble. flowering Peach, 5ft	1 6
*Genista anxantica, 5ft.	2 6	Weeping Laburnum, 6ft	2 6
*White Portugal Broom, 5ft	2 6	Eagle's-claw Maple, 6ft.	1 6
*Double Yellow Broom, 5ft	2 6	Lilac, rubra grandiflora fine plants, 6ft.	2 6
Robinia hispida major largest Rose Acacia, 6ft	2 6	Lilac, Charles X., do., 5ft	2 6

Female Plants (the fruit bearing plants), of the Shepherdia argentea, or Buffalo Berry, recently imported from America, 2*s*. 6*d*. each. "Its fruit, which is much relished in America, is about the size of the Red Currant, much richer to the taste, and forms one continued cluster on every branch and twig."—*London.*

Carriage of all Packages paid to London.

Those marked * are grafted on the Laburnum.

Sawbridgeworth, Jan. 31, 1844.

OLIVER'S "YOUNG HEIR" DAHLIA for 1844, to be sent out the last week in April, at 7*s*. 6*d*. each.

E. OLIVER begs respectfully to call the attention of Dahlia-growers to the above Seedling, which gained Prizes at the following places:—Felton open Show, best Seedling, Sept. 27, 1842; also an extra prize, August 31, 1843—nine blooms: Alnwick, August 29, in the first stand of 12; also the premier prize of any colour; also the best Seedling—five blooms. Colour, rosy crimson; the petal, form, and centre first-rate; constant and free bloomer; height, from 3 to 4 feet.

A few ground-roots to dispose of, at 3*l*. each. E. O. has no objection to take one-half of the amount in plants of anything new and good.—Ellington House, Whittingham, Northumberland.

GEO. CROFT, Forbury, Reading, begs to call particular attention to his Seedling Verbena "ADONIS"—a light crimson, with large lemon-coloured eye. This is particularly recommended to Noblemen and Gentlemen's Gardeners for planting out in beds, as nothing can excel in beauty a bed of this splendid Flower. Plants in April, 3*s*. 6*d*.

Likewise to his Seedling Fuchsia "UNIQUE"—tube and sepals smooth; sepals expand well; corolla, rosy purple: the plant is of beautiful habit, and if the Public can judge, then this is one of the loveliest Fuchsias sent out. Plants in April, 7*s*. 6*d*.

DAHLIAS.

J. KEYNES, Florist, Salisbury.—"Standard of Perfection," (Keynes).—The finest self-coloured Dahlia in the world! gained the 1st class prizes at Stonehenge, Windsor, Kingston, Surrey Zoological Gardens, and Crown and Anchor, Stockwell; also the 1st prize specimens at Stonehenge Floricultural Society, Stockwell. "It is as round as any Dahlia in cultivation; as complete an unbroken circle as could be drawn with the compasses; and as globular in front as possible. It is symmetrical to a hair, and as double as a Ranunculus. It is so remarkable as to be instantly recognised among a thousand. Colour, deep crimson. It is the flower of the season, and must be had."—*Gardeners' Gazette*, Oct. 14. "The best-grown flower we ever saw, without exception, every requisite to meet the taste of a connoisseur being complied with; good colour, a honeycomb, regularity of growth and disposition in the leaves, and above all, as complete a rotundity of shape as if it had been cast in a mould."—*Salisbury Herald*, Sept. 9, 1843. Plants in May, 1844, 10*s*. 6*d*. "Orange Superb," (Dodd's) first-rate show-flower, 10*s*. 6*d*. "The specimen sent would grace any stand."—Glenny. "Emma Noke," (Dowding's) bluish white, extra fine, indispensable to a first-rate stand, 10*s*. 6*d*. Catalogues containing all the fine old varieties and new flowers for the season may be had on application.—Salisbury, Jan. 30, 1844.

NEW EARLY POTATO.

HURST AND McMULLEN beg to inform the Public they have this season purchased of Mr. Soden, his entire stock of that splendid new Early Potato, *Soden's Early Oxford*. This superior variety has taken the *First* Prize at all the *three Shows at Oxford and other places*, and is allowed to be the earliest and best in cultivation. Sold at 4*s*. per peck, *bag included*. In another column will be found a List of choice Vegetable Seeds.

6, Leadenhall-street, Feb 1, 1844.

JOHN MILLER, surviving Partner of the late firm of Sweets and Miller, Nursery and Seedsmen, Bristol, begs respectfully to inform Nurserymen, the Trade, and his Friends in general, that he has commenced business as Auctioneer and Valuer of Horticultural and Agricultural Stock, &c., and hopes by strict attention to the interest of his employers, to merit their support. Letters addressed to John Miller, Portland House, Kingsdown, Bristol, will meet with immediate attention.—Bristol, January 31, 1844.

NEW HARDY ANNUAL.

VISCARIA OCULATA—DARK-EYED VISCARIA.

T. AND J. BACKHOUSE, Nursery and Seedsmen, York, have the pleasure of offering to the Public the above new and beautiful Annual, which is figured at page 52, (No. 10), of the "Botanical Register" for 1843. The blossoms are of a bright rose colour, with a deep crimson eye, and changing to a pale purple. It flowers very abundantly through the greater part of the summer and autumn. It is a native of Algiers and may be sown either in the open ground in spring, or raised in pots and planted out.

Packets, 2*s*. 6*d*. each, will be sent, on the receipt of a Post-office order, postage free, to any part of the Kingdom.

FINE HYBRIDIZED FUCHSIA SEED.

W. MILLER begs to inform his Friends that he has spared no pains in selecting the best kinds of Fuchsia for hybridising, and now has a few packets of the seeds to dispose of, in packets containing 100 seeds, 7*s*. 6*d*.; 50 seeds, 4*s*. Fine Verbena seed, in packets at 2*s*. 6*d*. and 5*s*. each, with directions for sowing. W. M.'s extensive list of Fuchsias, Verbenas, Pelargoniums, &c. &c. may be had on application, containing a full description of his new productions, by Dodd, Lemaire, &c.—Fuchsia "Constellation;" "Perseus" "Punctata;" Verbena "Blue Queen" and "Zenobia." W. M. has fine plants of his new "Fire Ball" Geranium, at 5*s*. each. The above will be sent post free to any part of the United Kingdom.—Providence Nursery, Ramsgate, Jan. 31, 1844.

DANE CROFT NURSERY, STOWMARKET, SUFFOLK.

SAMUEL GIRLING, English and Foreign DAHLIA AGENT, submits the following choice SELECTION of DAHLIAS to his numerous Friends for 1844, plants of which may be had early in May; they are all faithfully described, and early orders are respectfully solicited, as the stock of some of sorts is very limited. General Catalogues of DAHLIAS, GERANIUMS, PANSIES, FUCHSIAS, and VERBENAS, can shortly be had, on prepaid application.

BEAUTY OF SUFFOLK (Bass's).—Bronzy purple, of superior form and excellent habit; a constant and extra show-flower; seedling prizes at Ipswich and Stowmarket. Height 4 feet.—Price 7*s*. 6*d*.

BERMONDSEY BEE (Pascoe's).—A crimson purple, of excellent form and fine general habit, well cupped, and when well grown one of the best Half Dahlias in cultivation.—4 ft.—10*s*. 6*d*.

MODEL (Bourn's).—Dark purple, of first-rate form; has taken first prizes at the Metropolitan and other shows, and pronounced a first-class flower. 4 ft.—10*s*. 6*d*.

NONPAREIL (Pascoe's).—Ruby scarlet, of first-rate form, habit excellent, free bloomer, pronounced by the Horticultural Society of London, and at the Slough exhibition, to be a first-class flower. The stock of this beautiful Dahlia is limited, and unless it breaks well will be lost in another year. No allowance on this variety unless six plants are ordered. Glenny's opinion of this Dahlia is, that well grown it will be a trimmer. 4 ft.—10*s*. 6*d*.

ORANGE PERFECTION (Bourn's).—Of good form and colour, an extra second-rate show-flower, rather low in the centre, but sometimes well up, when it will beat all the Orange varieties. 4 to 5 ft.—7*s*. 6*d*.

RED ROVER (Girling's).—Of good general properties and extra fine habit; colour fine red, and useful for standards. 4 to 5 ft.—7*s*. 6*d*.

TALMA (Girling's).—Purplish rose, of superior form and little short of first-rate; rising centre and very constant. 4 ft.—7*s*. 6*d*.

SIR JOHN STEWART RICHARDSON (Union, in which Girling has a share), which is one of the most popular Dahlias of the season. No allowance on this variety unless 12 plants are ordered. 4 ft.—10*s*. 6*d*.

FANCY DAHLIAS.

CORNELIA (Girling's).—Purple, tipped with white; of good habit and very distinct. 4 ft.—5*s*.

GARLAND (Girling's).—With three colours—cream, sulphur, and brown tip; of good form and habit. 5 ft.—5*s*.

MADAME MIELLEZ (Girling's).—Rose-lilac, tipped or striped with white; a distinct variety, of good habit. 3 to 4 ft.—5*s*.

MADAME DE BERGHE (Girling's).—White edged with pink; a distinct and beautiful variety. 3 ft.—5*s*.

MADAME CHAUVIERE (Girling's).—Light crimson tipped with pure white; very constant, good shape, and one of the finest border Dahlias in cultivation. 4 ft.—5*s*.

VILLAGE MAID (Girling's).—Colours white and purple, distinctly and beautifully tipped; good habit, and superior border variety. 3 to 4 ft.—5*s*.—Stowmarket, Jan. 31, 1844.

BUSHELL'S Light Seedling Dahlia "EMMA."—Plants in May, 10*s*. 6*d*. Colour white, tipped with deep cherry; the petals, form, and centre, good; the largest, most constant, and free in flowering of any Dahlia yet propagated, and has obtained several prizes. "Pet Rival" Plants in May, 5*s*. Colour, purple maroon; fine cupped petal and free bloomer; exhibited in several winning stands last season. Kensington Nurs. Plants in May, 5*s*.; most constant Rose grown. To be had of Messrs. Ansell, Camden Town; S. Girling, Stowmarket; F. and A. Smith, Hackney; and J. Bushell, 13, Hall-place, Kensington-lane.

HYACINTHS AND GROWING STOCK.

HUMPHREYS'S COMPOUND, applicable to all Greenhouse Plants, to Hyacinths and other Bulbs, and to promote the germination of Seeds. Sold in bottles 1*s*. 6*d*. each, by Flanagan and Son, Mansion-house-street; Hurst and McMullen, Leadenhall-street; W. Glass, Bishopsgate-Within; Smith, Islington Nursery; Garraway and Co., Covent Garden; Batt and Rumsey, 41*a*, Strand; William and John Noble, Fleet-street; Sayer, Covent-garden; Charlwood, Tavistock-row; W. J. Nutting, 21, Cheapside; G. Lawrence, 18, Piccadilly; John Keenan, Great Russell-street, Covent Garden; Lockhart, 155, Cheapside; Shrivenewood, Pantheon; Miner, Adams, and Naab, 68, Strand; Twaites and Son, Islington; Thomas Ansell, Camden Town; Thomas Watkinson, Market-place, Manchester; W. E. Rundle, Plymouth; Dickson & Co., Edinburgh; Fowler, Lewis, Fiehn, Holmes, and Co., Sheffield; P. Lawson and Son, Edinburgh; and other leading Seedsmen in town and country. Wholesale Agents, Davy, Mackenrodt, and Co., 109, Upper Thames-st., London.

MARNOCK AND MANLEY'S CATALOGUE of NEW AND CHOICE FLOWER-SEEDS, and Particular Directions for the best Modes of Cultivation, with the Treatise on the Winter-hardy Cauliflower is now ready, and may be had on application.

Their Stock of trained Fruit-trees are exceedingly fine, consisting of all the leading varieties of Peaches, Nectarines, Apricots, Plums, &c. Also the following Cherries:—Harrison's Heart, Black Heart, Adam's Crown, Waterloo, Knight's Early Black, Florence, Black Eagle, Downton, Late Duke, May Duke, Bigarreau, Elton Napoleon, Early Purple, Circassian, Kentish, Morello of sorts, &c. Prices may be had on application at their Nursery, Hackney, London.—Jan. 31, 1844.

FASTOLFF RASPBERRY.

YOUELL AND Co. have much pleasure in announcing they have now ready for sending to any part of the United Kingdom, fine Canes of the above highly valuable and much-esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour.

IT IS PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, THE MOST NOBLE THE MARQUIS OF AILSA, HIS GRACE THE DUKE OF RUTLAND, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

For further particulars they beg to refer to their Advertisement of the 27th of January: Prices as follows:—

Packages containing			£	s.	d.
100 Canes	.	.	1	0	0
Do. 50 do.	.	.	0	5	0
Do. 25 do.	.	.	0	14	0

Package included.

The usual discount to the Trade, when not less than 200 are ordered.

*** CAUTION.—Y. and Co. beg to call the attention of their Friends and the Public in general to the fact that they have appointed no Agents in London for the sale of the above, and cannot be held responsible for its being genuine, unless purchased direct from their Nursery.

YOUELL'S TOBOLSK RHUBARB, Patronised by Her Most Gracious MAJESTY the QUEEN, and many of the Nobility, 12s. per dozen.—For particulars of which see their Advertisement of the 18th November.

TWO NEW SEEDLING PICOTEES.—"LADY ALICE PEEL," 10s. 6d., and "MRS. BENTON," 10s. 6d. per pair.—These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, and kindly presented by that gentleman to Messrs. YOUELL and Co., for particulars of which see their Advertisement in this Paper of the 10th of Sept.

FINEST CARNATIONS AND PICOTEES.

YOUELL AND CO. beg to refer the readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation.

Prices as follows:—

	£	s.	d.
12 pair of good Show Sorts	1	4	0
12 ditto fine ditto	1	10	0
25 ditto ditto	3	0	0
12 ditto extra fine and very superior ditto ..	2	10	0
25 ditto ditto ditto ..	5	0	0

The selection being left to YOUELL and Co.

FUCHSIAS.

1 dozen of the newest and very best sorts ..	21s.
1 dozen fine ditto	12s.
1 dozen good show varieties	8s.

Sent by post, free, to any part of the United Kingdom.

ARAUCARIA IMBRICATA.

YOUELL AND CO., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms:—Fine robust 4-year-old plants, 8 to 9 inches high, 10s. per 100, or 20s. per dozen.—Great Yarmouth Nursery, Feb. 1, 1844.

FUCHSIA SEED.

YOUELL AND CO. beg to inform their Friends and the Public they have succeeded in saving a small quantity of the above from the very newest and best varieties, which they offer upon the following terms:—

A packet containing	100 seeds	10s.
Do.	50 do.	6s.

Sent post free on the receipt of a Post-office order. Directions for sowing, &c. will accompany each packet.

This will form an admirable opportunity to those who intend competing for Seedling Prizes at the exhibitions of the present year. The quantities being very limited, early application will be necessary.—Great Yarmouth Nursery, Feb. 1, 1844.

GAINES'S NEW AND FIRST-RATE PELARGONIUMS now ready for delivery in strong, healthy Plants. The following are a few selected:—Gaines's Elegans novus, King of Bedders, Acklam, Lady Prudhoe, Saxon King, Excelsa, Beauty Supreme, Mogul, Edith, Countess of Zetland, Cotherstone, Egbert. A list of Pelargoniums, Pansies, Calceolarias, Fuchsias, Verbenas, Auriculas, Cinerarias, Chrysanthemums, Dahlias, &c., which contains many new Seedlings of first-rate qualities; plants in May, 10s. 6d.; also a few roots of his Seedling Dahlias PRINCESS ALICE and TWICKENHAM RIVAL are still to be disposed of at the Nursery, Surrey-lane, Battersea.

FLORISTS' FLOWERS.—As the season for planting Ranunculuses is now on, J. and W. PINLAYSON, Florists, Paisley, respectfully intimate to the admirers of that beautiful flower and to Florists in general, that they have at present an excellent stock of their Splendid New Varieties, which they now offer for sale at greatly reduced prices, viz.—

		£	s.	d.
50 superfine sorts, one root of each		3	0	0
50 " " one pair of each		5	5	0

Many of these have been sold at 5s. to 10s. 6d. per root, and their superiority over the old sorts is always apparent at competitions, where they invariably carried off the prizes. Also a Splendid Collection of Auriculas, comprising most of the leading sorts in the country, with many new and rare varieties. Also Polyanthuses, Pinks, Pansies, Carnations, Dahlias, Tulips, Phloxes, Antirrhinums, Herbaceous plants, &c. &c. Catalogues may be had on application, post paid. A remittance or reference will be required from unknown correspondents.

TO GENTLEMEN PLANTING.

J. AND J. FAIRBAIRN are induced from the uncertainty upon which they hold the Manor-street Nursery (situated contiguous to the Home Nursery, Clapham Rise, where attention will be given to all applications), to effect a Sale of the Stock at as early a period as possible, consequently beg to solicit the attention of Gentlemen and the trade to the large and remarkably healthy and well-grown stock, consisting of fine large Laurels, twice transplanted, of extra growth; Portugal Laurels, very handsome; Green Hollies, of various sizes; Evergreen Privets, fine Standard and Dwarf Roses in great variety, fine standard fencing Thorns, Almonds, Æsculus, Robinias, and other Ornamental Trees, and Evergreen and flowering Shrubs, with a large stock of fine standard and dwarf, trained and untrained Peaches, Nectarines, Apples, Pears, Plums, and Cherries, of the most approved kinds, and of growth rarely equalled; also, a large assortment of Forest Trees, consisting of Limes, Elms, Birch, Beech, Hornbeam, Spanish and Horse Chesnuts, Mountain Ash, Poplars, and Spruce, and Scotch Firs, also a large number of Gooseberries and Currants, of excellent growth, and of the best varieties in cultivation, to all of which J. & J. F. respectfully invite the inspection of Gentlemen and Nurserymen, flattering themselves that the general character of the Stock is such as to ensure unqualified satisfaction, and which they are disposed to offer at very moderate prices for cash.

J. & J. F. respectfully beg to call the attention of Gentlemen to their advertisement of Heaths, &c., which has lately appeared in the *Gardeners' Chronicle*. (Oct. 21 and 28.)

Nurseries, Clapham, near London, Jan. 31, 1844.

SPLENDID NEW SEEDLING CINERARIAS.—Fine early-flowering strong plants of CINERARIAS, saved from the very choicest sorts of blue and crimson colours, selected from between five and six thousand Seedlings of last year. Those purchasing will have an opportunity of flowering some of the choicest sorts in cultivation, remarkably healthy, and having a large stock they can be sold at 2s. and 1s. per dozen, carefully packed for any part of the country. Applications including Post-office orders will be immediately executed. Large bunches of RUSSIAN VIOLETS in full flower, fit for potting, 6s. and 9s. per doz.—Direct to MICHAEL BARNES, Sen., Cambridge Nursery.

TO GENTLEMEN and AMATEUR FLORISTS.—As the return of spring is fast approaching, so is the planting of that beautiful flower the RANUNCULUS. A few hundred roots to be parted with (with names), and a single root of the very high-coloured purple flower "Quixos," will be included in each hundred roots; the time of planting, February and March. Apply, pre-paid, to Mr. EVANS, Farnham, Surrey, where may be seen, in the blooming season, in Mr. EVANS's Collection of PELARGONIUMS, the Seedlings, and other specimens of this most delightful, still improving flower.—Farnham, Surrey, Jan. 31.

J. KERNAN has now received his entire Collection of New VEGETABLE and FLOWER-SEEDS, which includes every Novelty really desirous, recently introduced:—

	s.	d.
Fine Early Kent Peas, per quart	1	0
Prince Albert do.	3	6
Racehorse do.	1	0
Early Warwick do.	1	0
Shilling's new Grotto do.	3	0
Thompson's Early Dwarf ditto	1	6
Stubbs' New Dwarf do.	1	6
Groom's Superb ditto	1	0
Knight's Dwarf Green do.	1	0
" tall do.	1	0
Victoria Marrow	1	0
Bishop's Dwarf do.	1	0
Nonesuch do.	0	9
British Queen do.	3	6
Matchless do.	1	0
Bedman's Imperial do.	0	9
Scimetar ditto	0	9
Early Mazagan Beans	0	6
" Longpod do.	0	8
Royal Dwarf do.	0	8
Green Genoa do.	0	9
Large Windsor do.	0	9
Dwarf French, of all sorts	1	0
Mercer's Pearly Cauliflower per oz.	1	0
Walcheren ditto	1	0
Large Asiatic ditto	1	0
Early Horn Carrot, per oz.	0	4
Surrey do.	0	4
Altringham, and large White, for Cattle, per lb.	1	0
Seymour's New Superb Red and White Celery, per paper	0	6
Myatt's Cape Broccoli, per oz.	1	0
Grainge's do.	1	0
And all the other kinds, " 9d. to	1	0
Brussels Sprouts, foreign seed	1	0
Acme of Perfection Cucumber, finest known, per paper	1	0
Kerrison's, Walker's, and Sion House ditto	1	0
New Cabul Melon, per paper	1	0
Windsor Prize, Sion-House, Greenflesh, Netted Cantalonpe, Black Rock, &c. &c.	0	6
New Olive Radish, fit in 18 days in a frame	1	0
Early Salmon and Scarlet do., per quart	2	0
All the best keeping Onions, per oz.	0	6
Imported Early Dutch Turnip	0	3
Ash-leaf and Early Frame Potatoes, with several good-keeping kinds; Very Choicest Grasses (hand-picked), for Lawns; all the most beneficial kinds for laying down. Separate or mixed; if mixed, per bushel	10	0
Tuberoses, per dozen	4	0
Anemones, per lb., 5s. to	20	0
Lilium lancifolium album, flowering-bulbs, each	3	6
Lilium speciosum, strong, true	31	6
" lancifolium punctata	7	6
" superbum, flowering	2	6
" eximium	1	0
Giant Asparagus, 2 yrs., per 100	6	0
" Sea Kale	10	0
Mushroom Spawn, per bushel	0	0
Skirving and Laing Swede Turnips	1	6

With all the other new kinds.

Dulley's Early Scarlet Admirable Rhubarb; all the new Strawberry Plants, true to their kinds.

Heartsease, Picotees, and Carnations, named; Rivers' New Edition of the Rose Amateurs' Guide, 6s.

Rivers' Catalogue of Fruits, with directions for Culture, by foot-pruning, 1s 6d.

Paxton's Cottagers' Calendar, 3d., which Ladies and Gentlemen should present to Cottagers.

Seeds for Distribution to Cottagers at cost price.

Seed of Dwarf Furze and Broom; Seedling Barberries for Underwood. Spring Tares.

Everything new in Flower-seeds, of which Catalogues will soon be ready.—4, Great Russell-street, Covent Garden.

RANUNCULUSES, ANEMONES, CARNATIONS, AURICULAS and LILIUM LANCIFOLIUM.

H. GROOM, Clapham-rise, near London (removed from Walworth), by appointment FLORIST TO HER MAJESTY, begs to remind the Nobility, Gentry, and Amateurs, that this is the best season for obtaining Collections of the above Flowers, and that in consequence of the success he had in their cultivation last year, he can offer them at the following moderate prices:—

	£	s.	d.
100 Ranunculuses in 100 superb sorts with names	4	4	0
100 do. in 100 very fine sorts, do.	2	10	0
Superfine mixtures, from 7s. to 21s. per 100.			
100 Anemones in 100 superfine sorts, with names	2	10	0
100 Do. in 50 do. do.	2	0	0
Superfine mixtures, 10s per 100.			
25 pair of Carnations, in 25 superfine sorts, with names	3	10	0
25 pair of Picotees, in 25 do. do. do.	2	10	0
25 Auriculas, in 25 superfine sorts, with names	3	13	6
Lilium lancifolium album, good bulbs, each	0	3	6
" " " large bulbs, each	0	10	6
" " punctatum, good bulbs, each	0	7	6
" " " large bulbs, each	1	1	0

Catalogues may be had on application.—Jan., 1844.

ANEMONES AND RANUNCULUSES.—The entire Stock of an Amateur Florist, who has spared no expense in procuring the finest sorts, but whose garden having been sold for building purposes, is compelled to part with them, and offers them on the following terms:—

RANUNCULUSES

100 Roots, finest sorts, double, named flowers	21s.
50 extra extra ditto	15s.
100 fine ditto in mixture	8s.
100 ditto, second quality	5s.
50 Tyso's best semi-double ditto for seed	4s.
Packets of 300 seeds saved last year	1s. 6d.

Packets of 300 seeds saved last year 1s. 6d.

Any of the above will be sent post paid on receiving a remittance by Post-office order, or letter stamps to the amount wanted.

ANEMONES.

100 Splendid, named, double flowers	21s.
50 extra fine ditto	12s.
100 fine ditto in mixture	7s.
50 fine scarlet ditto in mixtures	8s.
Packets of seeds, each	1s.

Apply to S. G. LAING, Wine-merchant, Dundee.

EARLY PEAS, &c.—HENRY D. CORMACK, EXHIBITOR, &c., begs to inform the readers of the *Gardeners' Chronicle* that they can be supplied with the following Early and Prolific Varieties, viz.: Cormack's Prince Albert, British Queen and Early Kent Peas; Taylor's Improved Windsor, and Johnson's Wonderful Bean; Manchester Red and Seymour's White Celery; Walker's Long and Hamilton's Cucumber, &c., with every other variety of Horticultural and Agricultural Seeds, at his Wholesale and Retail Seed Warehouse, 100, Deansgate, Manchester.

SHILLING'S EARLY GROTTO PEA.

J. AND S. SHILLING have succeeded in raising the above PEA, the Early Frame Pea, impregnated with the Grotto or Oyster Marrow, which they, with confidence, recommend to the Public generally, being quite as early, and nearly double the size of any other Pea in cultivation. Quite hardy, will stand the winter well, and a good bearer; the pod large and long. They would particularly recommend it to the attention of Market Gardeners. Price 3s. per quart; 10s. per gallon; 17s. 6d. per peck; 30s. per half-bushel; 2l. 10s. per bushel. Agents:—Messrs. FIELD and CHILD, 119, Lower Thames-street, London; Messrs. W. and J. NOBLE, 152, Fleet street; Mr. KENNAN, 4, Great Russell-street, Covent Garden; Messrs. HURST and McMULLEN, 61, Leadenhall-street; Messrs. GRAY, ADAMS, and HOGG, Kensington; Mr. T. D. WATKINSON, Market-place, Manchester.—Northwarnborough Nursery, near Odiham, Hants.

THE BRITISH QUEEN AND PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above two new Varieties, the merits of which are thus noticed in the *Gardeners' Chronicle*. "THE BRITISH QUEEN on light soils, is the best of all kinds, and will drive Knight's Tall Marrow out of the garden." "THE PRINCE ALBERT, which has been cultivated in the Garden of the Horticultural Society during the season, produced Peas fit for the table *ten days earlier* than any other variety sown at the same time." Both varieties may be had in packages at 3s. 6d. each, at W. J. C.'s wholesale Establishment, Newcross, or the Bedford Conservatory, Covent Garden.

THE undermentioned, with a select Assortment of FLOWER and other GARDEN SEEDS, may be had now, as annually received from the respective growers, at moderate prices, from THOS. D. WATKINSON, ORIGINAL SEED ESTABLISHMENT, 6, Market-place, Manchester:—New Early Dwarf Thompsonian Peas, a prolific bearer; Shilling's New Early Grotto; Prince Albert; Knight's Marrow, &c. True Johnson's Wonderful Beans; Large Improved Windsor, Myatt's Treble-curled Parsley; True Walcheren Cauliflower Broccoli; Cuthill's Long Black Spine and Manchester Improved Long Frame Cucumber; Whyte's extra fine Dwarf Red Beet; True Altringham Carrot; and superior Yellow Garden Turnip; Ashleaved forcing Kidneys and other Early Potatoes; Extra fine Red and Pink, Lancashire Giant, Solid, and Seymour's superior White Celery; Tobacco Paper; Mushroom Spawn, &c. &c. Catalogues on application.

Agent for Whitney's Waterproof Composition and Humphrey's Compound. May's Select Pansy and Hollyhock Seed, in packets at 2s 6d. and 5s. each.

R. WHITE & Co.'s Collection of Plants, of which a Catalogue is now in the press and will be ready in about a week, comprises every variety of Geranium, Fuchsia, Verbena, Chrysanthemum, Dahlia, &c. which is worthy of cultivation. The following collections are offered, the selection being left to the purchaser:—

		£	s.	d.
40 first-rate varieties of Geranium		5	0	0
20 " " do.		3	0	0
12 " " New do.		3	0	0
20 " " Fuchsia		1	1	0
40 " " Chrysanthemum		1	1	0
20 " " Verbena, including Seedlings which were submitted to Dr. Lindley for his opinion, and reported to be "all very fine," see *Gardeners' Chronicle*		1	1	0
12 first-rate Dahlias	Alfred	1	1	0
100 fine show do.		2	10	0

The above will be ready for delivery in strong plants the first weeks of April and May; and orders containing remittances will be executed in strict priority. Orders amounting to 5l. will be delivered free.—WANTED, a RESPECTABLE YOUTH as APPRENTICE.—Poole Nursery.

CAMBERWELL.—CAMDEN NURSERY GROUNDS.

MESSRS. ELLIS AND SON will SELL by AUCTION, on the above Premises, near Camden Chapel, Peckham-road, on Tuesday, the 6th of February, and following day at 11, on account of the number of lots, under distress for rent, the entire STOCK, Buildings, and Tools; consisting of two capital Greenhouses, 26 feet in length, heated by hot-water-pipes, forcing pits, Cucumber and hand-lights, Shop fixtures, a case of 150 drawers labelled for seeds, and sundry tools. The stock includes an extensive assortment of standard and wall-fruit trees, a great variety of well-selected Roses, Geraniums, and Greenhouse plants, Picotees, Auriculas, Dahlias, Jessamine, Myrtles, Camellias, American plants, Shrubs, and Evergreens, some good specimens of Ornamental trees, and fine Mulberries, a number of Gooseberry and Currant trees, various seeds, &c. To be viewed three days prior to the sale. Catalogues may be had on the premises; at the Horns, Kennington; of Messrs. Fairbairn, nurserymen, Clapham rise; of Messrs. Forrest and Co. nurserymen, Kensington-road; and of Messrs. ELLIS and SON, auctioneers, 36, Fenchurch-street.

VALUABLE NURSERY STOCK, IVER HEATH, BUCKS.

MESSRS. SEDGWICK AND SON have received instructions to Sell by Auction, on the Premises, near the Crooked Billet, on Iver Heath, on Monday, February 12, at Eleven, in convenient Lots,

About 2000 fine PORTUGAL and other LAURELS from 1 to 8 feet, a very large and choice collection of standard and dwarf Apple, Pear, and Cherry trees; some very handsome Yew plants of good growth, Larch, Spruce, and Scotch Firs; seedling Oak and other Forest trees, plain and variegated Box, Arbutus, Privet, and other Forest trees, plain and variegated Box, Arbutus, Privet, Laburnums, Scarlet Thorn, Lilacs, Roses, &c. &c. &c., in the Nursery adjoining the road leading from Uxbridge to Langley.

May be viewed four days prior to the sale (Sunday excepted), when catalogues may be had at the Crooked Billet, Iver Heath; at the principal Inns in the neighbourhood; at the King's Arms Inn, Oxford Street, London; and of Messrs. SEDGWICK and SON, land and timber surveyors and estate agents, Rickmansworth, Herts.

TO GENTLEMEN AND OTHERS ENGAGED IN PLANTING.

MESSRS. PROTHEROE and MORRIS are instructed by the Proprietors to submit to public competition, in consequence of the expiration of lease, on MONDAY, MARCH 4, 1844, and following days, at 11 o'Clock, THE STOCK OF ONE OF THE KENSINGTON NURSERIES, next the Great West Road, consisting of large, healthy, and well-grown Specimens of Ornamental Trees and Shrubs, of every description, Variegated and Green Hollies, Evergreen Oaks, and Cork-trees, Large Fan and other Yews, twice-transplanted Common and Portugal Laurels, Arbutus, Alaternus, &c., Hemlock Spruce, Pinus Laricio, P. austriaca, and nigricans, &c. &c. These Grounds have long been celebrated for the Health and Beauty of their Trees and Shrubs, and safety of removal, and well worth the attention of those Gentlemen who intend Planting in the spring. American Nursery, Leytonstone.

In an Advertisement of Messrs. PROTHEROE & MORRIS inserted in this Paper of last week, it is stated that these gentlemen have instructions from the proprietors to offer for sale the stock of "One of the KENSINGTON NURSERIES next the Great West Road." As our Nursery is situated next the Great West Road, and a great part of it is in the parish of Kensington, it is known to many of our customers by the name of "The Kensington Nursery," and the names of the proprietors not being given in the Advertisement, they may naturally suppose that it is our stock which is to be sold. We therefore inform them that such is not the case, but that we are prepared, as usual, to execute their esteemed orders, which shall be attended to with the greatest possible care and promptitude.—GRAY, ADAMS, and HOGG. Brompton Park, Kensington Road, Feb. 1844.

HORTICULTURAL SOCIETY OF LONDON.—Notice is hereby given that the Exhibitions of Flowers and Fruit, in the Society's Garden, in the ensuing season, will take place on the following Saturdays, viz., May 18, June 15, and July 13. In addition to the regulations already announced, it has been resolved that the Judges be instructed, in making their awards, to take into consideration, whether the Plants to be judged have been exhibited previously during the season. Full information concerning these Exhibitions can be obtained upon application at 21, Regent-st.

GARDENERS' CHRONICLE.—Wanted a clean and perfect Copy of the 1st and 2d vols. of the *Gardeners' Chronicle*; any one having the same to dispose of (or a complete set) will receive immediate attention on stating price, &c. to Mr. W. T. JACKSON, Bookseller, Bury St. Edmunds.

WARNER AND WARNER, SEEDSMEN, 28, Cornhill, London, beg respectfully to refer their Friends to "Harrison's Floricultural Cabinet" for February, for their Advertisement of New and Select VEGETABLE and FLOWER SEEDS. Catalogues may be had on application. POTTER'S CELEBRATED LIQUID GUANO, in quart bottles, at 1s. 6d. each.

The Gardeners' Chronicle.

SATURDAY, FEBRUARY 3, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Monday, Feb. 5 ..	Entomological	8 P.M.
Tuesday, Feb. 6	Linnean	8 P.M.
Wednesday, Feb. 7	Society of Arts	8 P.M.
Thursday, Feb. 15	Microscopical	7 P.M.

THE causes of the DISEASES OF PLANTS, like those of animals, may be divided into the *predisposing* and *exciting*. To the predisposing causes must be referred all those peculiarities in the structure and growth of a plant that would render it more liable to be attacked by disease than other individuals. Thus it is found that many varieties and species of plants, from primitive constitution and other causes, are more liable to certain diseases than others. These causes, then, which are frequently most obscure, are predisposing. They should not, however, be lost sight of, as it is an important fact to know that particular varieties or species are most subject to disease. The exciting causes of disease in plants are the increase, decrease, or alteration of the various external agents by which their life is maintained; these agents are light, heat, electricity, air, water, and the soil. It is through their action that the functions of life are carried on, and the plant grows and continues its species. In a state of nature the constitution of plants is adapted to the distribution of these agents on the globe, so that disease is not often met with in those which are wild; but when plants become cultivated, their natural relation to these agents is disturbed; and, like civilised man and domesticated animals, they become the subjects of disease. This does not, however, arise from any positive necessity, but from our ignorance of the precise circumstances by which health may be secured.

In endeavouring to estimate the influence of these agents on the production of disease, it should not be forgotten that diseases may arise from a complication of causes, and not simply from the too great or too little influence of one of the agents. Thus the deprivation of heat may act on plants growing on a bad soil when it would not on those growing on a good one. This will explain many apparent anomalies in the prevalence of epidemic diseases in plants, and will also point out the importance, in reporting cases of diseases in plants, of recording *all the circumstances in the history and position of the plant that can affect its structure or functions.*

The influence of *light* is very great on the healthy growth of plants; it acts as a stimulant, and by its agency the peculiar secretions of plants are almost entirely developed. When deprived of it, what is called *blanching* takes place. This is a disease of the plant, though purposely had recourse to in many gardening operations. Its effect is constantly produced to a greater or less extent on plants grown in this country which are natives of tropical climates, and it often lays the foundation of other diseases. Disease may also occur from excess of light, where plants growing naturally in dark shady situations are exposed to its influence.

Temperature has a more obvious influence on the health of plants than light. The diseases produced by a low temperature are very numerous, and there is no agent that plants will bear the diminution of so little as heat. Much depends on the circumstances of the plants. After the buds have expanded, the parts of the plant appear to bear cold better, the older they are. Frosts often deprive the stamens and pistils of flowers of their functions, and unfruitfulness is the result; leaves are spotted, and canker of the stem and branches are often produced by it. Plants never get inured to cold, for their structure does not appear to possess the adaptability of animals; and consequently, when brought from climates where the average temperature is higher than our own, they are sure, at one time or another, to suffer. Excess of heat frequently produces disease, although its consequences are very slight compared with those of cold. Sudden changes from hot to cold affect the secretions of plants, and to this cause honey-dew is almost frequently to be attributed.

A due supply of *water* in the form of vapour in the atmosphere, and liquid in the soil, is necessary to most plants; but when either in too large or too small quantities, it is the cause of disease. Anasarca, or dropsy, occurs where there is too much moisture in the air; and the excessive development of hairs on particular parts of the plant is a consequence of dry air. When in too large quantities in the soil, canker, a premature falling of the leaves, and other diseases, are the consequence. Withering, and also a falling off of the leaves, is the consequence of too little water.

What influence the composition of the *soil* has on particular diseases of plants we are not in a position to state. Matters which are in excess in the soil are frequently taken up by plants and thrown out again as excretions on the surface. Thus, an excess of salt is often got rid of in the form of an excretion on the leaves by plants growing on the sea-shore. The want of particular ingredients will, it is well known, prevent plants from growing; but what the diseases are they suffer from is at present but little known.

Through the medium of the soil and air, various poisonous agents are introduced to plants. From this cause arise important effects requiring investigation. The precise influence of carburetted hydrogen, chlorine, sulphurous acid, and the gases in the air, is not known; and in the neighbourhood of towns a variety of injurious ingredients get into the soil which are destructive to vegetation.

To the influence of each of the above agents in producing disease we might have devoted a separate article, but our object has been to point out what are the causes of diseases rather than to give any lengthened account of them, in order that our readers may at once begin to co-operate with us in investigating the diseases of plants. When we proceed to describe particularly each disease, we shall have frequent occasion to refer at length to the causes of the departure from health in plants.

With regard to the treatment of diseases of plants, we shall have abundant reason to see that prevention is better than cure. Nevertheless, a knowledge of the causes of disease will frequently enable us, by removing them, to cure them; and this is more particularly the case with shrubs and trees. No treatment, however, can hold out any chance of success that is not founded upon a knowledge of the functions obstructed in diseased parts, and the causes which have contributed to such obstruction. We shall be glad of any communications on the subject of the treatment of diseases of plants, and hope our correspondents will remember that unsuccessful cases are equally valuable with successful ones.—*L. E.*

MOST heavy-land farmers know the value of PARING and BURNING their land. Experience has shown that no operation is to be compared to this for improving the fertility of soil. Gardeners, however, have been but little accustomed to practise it, and usually resort to other means, which, if as effectual, are far more expensive; for burning clay, if properly conducted, has the great merit of costing nothing beyond a little labour.

Why burnt clay should be better than that sort of soil in its ordinary condition, is sufficiently obvious. Its texture is changed. In its natural state it is so adhesive, that air cannot get into it, nor water out of it. It also offers great mechanical opposition to the passage of roots through its viscid mass, and hence it is exclusively inhabited by a coarse and worthless vegetation. Burning changes all this; the particles of clay lose their adhesiveness, and this alone gives a new character to the soil, which offers freedom to the entrance of air and exit of water, and which crumbles readily away beneath the advancing roots of a soft and succulent race of plants.

Such changes are in themselves most important; but this is not all the difference between burnt and unburnt clay. The roots of plants, which were before unable to decay, are reduced by fire to their saline constituents, and so enrich the land. And, moreover, the burnt particles of clay acquire the power of absorbing ammonia from the air, and holding it within their pores till showers fall and wash it into the land, where it immediately acts as a nourishing food to the crops.

The employment of burnt clay in gardens has, perhaps, been neglected in consequence of a supposed difficulty in conducting the operation. In our volume for 1843 we gave an account of a simple method by which large masses of clay may be set on fire for farming purposes; and we now publish the following excellent practical letter from Mr. W. Paul, of Cheshunt, in which his mode of proceeding and the results of it are explained.

It has been the custom here for some years, in spring, when the operations of pruning, &c. are ended, instead of suffering the rough branches to lie about, presenting an untidy appearance, to collect them in a heap, and build a wall of turf round them in a semicircular form about three feet high. They are then set fire to, and when about half burnt down, such weeds and other rubbish as collect in every garden, and will not readily decompose, are thrown on the top, and earth is gradually cast up as the fire breaks through.

During the first two or three days no ordinary care is requisite to keep the pile on fire, but after this, if the fire is not allowed to break through and thus expend itself, it will certainly spread through the whole heap, and almost any amount of soil may be burnt by still adding to the top. The soil we burn is the stiffest loam that can be found within our limits, and is rather of a clayey nature; also turf from the sides of ditches and ponds, in itself naturally sour and full of rank weeds.

The clay thus burnt has been found beneficial in every instance. In black garden-mould, where Peach-trees were disposed to sucker and canker, despite of animal manures and drainage, two or three annual dressings of burnt earth appear so to have altered the soil that they now grow clean, vigorous and healthy, are free from suckers, and produce roots completely matted with fibre. The like success has attended its application to other fruit-trees.

During the summer of 1842, six beds of Tea-scented Roses growing in an alluvial loam (the adjacent fields are of the same soil, and grow large crops of Wheat and Potatoes, but the particles of soil run together after rain, and present a smooth cemented surface) were manured with the following substances, viz., 1, bone-dust; 2, burnt earth; 3, nitrate of soda; 4, guano; 5, pigeon-dung; and 6, decomposed stable-manure. The guano produced the earliest visible effects, causing a vigorous growth, which continued through the season; the flowers, however, were not so abundant, and the shoots did not ripen well, and were consequently much cut with the frost. The bed manured with burnt earth next forced itself into notice; the plants kept up a steadier rate of growth, producing abundance of clean, well-formed blossoms; the wood ripened well, and sustained no injury during winter. The results of the other manures were not remarkable—acting as gentle stimulants, the nitrate of soda and bone-dust least visibly so—although they were applied in the quantities usually recommended by the vendors.

From the fact of the beds of Roses being all planted at the same date, and their progress being carefully watched, I would suggest the application of burnt earth as an excellent manure for Roses in adhesive soils, as well as for fruit-trees where disposed to canker. Whether it acted by furthering drainage, or by opening the soil to the fertilizing influences of the atmosphere, or by fixing the ammonia conveyed to the soil by rain, I do not pretend to say, but its value is sufficiently apparent. I believe it is considered that the vegetable matter contained in soils is destroyed by the act of burning; and I do not think the remains of the materials used in combustion could exercise any extended influence, as the quantity compared with the earth burned is so small, and the earth comes from the heap burnt red and hard, and a great portion quite free from the remains of the substances used in ignition.

Our readers will remember Mr. Rivers's advice about roasting turf, of the use of which this is a confirmation. It is perhaps as well to add, that burning is more injurious than advantageous to light soil.

THE ROSE GARDEN.—No. III.

(*Continued from page* 53.)

The following, which was taken from the side of a road from whence it was observed, may be considered as an extraordinary specimen for height, shape, health, size, and vigour.

The stem perfectly straight, with 36 branches upon it, many of which had side-shoots upon them; but as one-half of these were cut off in removing the head, and the remainder were close below them, the stock itself being very close-jointed, and the lower branches small, they formed little or no objection to the stem when removed.

When replanted, the height of the shoot was five feet one inch from the ground; it then divided itself into four branches, which were left for budding upon. The circumference at the base being four inches and a quarter, the centre three inches and a quarter, and at five feet one inch from the ground, two inches nine-sixteenths, the base being the largest part of the plant, which diminished gradually to the top.

The species was the green and brown, or grey striped, the prickles similar to those of the Eglantine in regularity; the wood so clean, that there was not a speck upon it, and the whole appearance that of an extremely healthy and vigorous plant of three seasons; its strongest shoots the autumnals of the present year, and near the top of the head; evidently showing that the sap was not likely to desert the stock and escape in suckers the next year. The root was, however, large, and furnished with but two or three fibres, which were found quite sufficient to maintain the plant in full vigour when moved. The branches left for working were not, however, fit for the purpose for want of a sufficient flow of sap, and were removed in the winter; but had they been taken off in the first instance, young wood would undoubtedly have been formed fit for use. From two feet six to three feet high to the first branch, and one inch three-quarters in circumference, may be considered a good size (very much above the average) for plants at their best, viz., either as ripened suckers of the current, or seasoned ones of the preceding, year.

The French Stocks are considered far superior to the English, and in consequence, when worked, afford an article of much commerce between the two countries; in France more trouble is bestowed upon worked Roses, as well as a more practical degree of knowledge. A large quantity of Stocks are placed in pots, and plunged for working, by which the roots are probably multiplied, (a circumstance in general the case in confined spaces, by which nature makes up to a certain degree for extent,) and

the branches are seldom mangled after having been worked. The climate alone, however, would be sufficient to account for a material difference between the produce of the two countries.

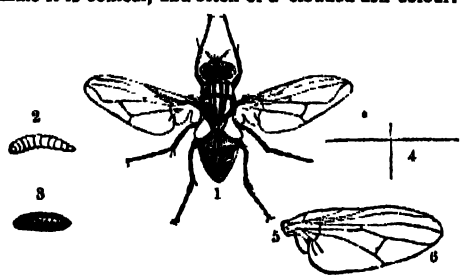
It is worth the while of an Amateur to observe an importation of unpotted French Rose trees on their arrival. If the lot be a picked one, he would hardly recognise the plants to be of the same species as those upon which he had been accustomed to operate, or believe the head produced upon them to be the growth of a single year. If, however, he is tempted to buy, not only the heads and stems must be taken into consideration, but the roots also—the French are in the habit of budding in hedges, and of removing the plant from thence for sale. If several suckers have arisen from the same root, and all but one be cut away, it is evident that the stem so left will receive the nourishment of the whole root; and if a bud be placed on such stem it will form a complete head in one season; yet when the plant is removed, the root will be found far too large, woody, and unsupplied with fibres for transplantation in its present shape, and when reduced and removed, its vitality may be destroyed, and must be injured, and it is not therefore likely to maintain the head it carries during the present year, in vigorous health through the next.

The largest Stocks are those which have an oval fruit, (they are called indiscriminately, Dog Roses, Buckbriars, Hangbriars, &c. by the countrymen, though the varieties are endless); with these, if the height be proportioned to the size, no support is necessary even when the tree is complete, unless the head be very large; but as different Roses require different Stocks, this advantage with some species of Rose cannot be obtained.

The produce of one hedge will be found to differ from that of another most materially, both as to size, height, woodiness, colour, mode of growth, &c.: some being covered with prickles like the Eglantine, some with prickles more dispersed, some have the bushy growth of the common China, shooting apparently from one joint just below the soil; others with a confused root like the small species of Lilac; some travelling over space after space by means of suckers; some with compact, others with straggling heads; some places appear to produce nothing but inferior stocks; others none but the tallest and stoutest.

The small green round-berried stocks are least able to resist the frost; they are, in consequence, planted double the height required, left to grow as they please, and budded a foot from the ground in the stem instead of the shoot, which the thinness and flexibility of the bark renders extremely easy, being thus suited for pots, &c.

Youth, as above stated, is not a matter to be insisted upon, but as all young plants of the wild Rose will generally be found to possess the most fibrous roots, they are in consequence more likely to maintain their power of free growth when transplanted than old ones.



(To be continued.)

ENTOMOLOGY.

The House Flies.—Amongst domestic plagues flies are generally included. Few persons know from whence they come, or are aware that there are numerous species which inhabit our dwellings; some a good deal resemble each other, it is true, whilst a few are so very dissimilar, that, even to the indifferent observer, there is such a marked disproportion in size, that the smaller ones are at once pronounced to be the young of the larger individuals. In our days, when Natural Science has arrived at such a degree of perfection as it had never previously attained—when every year, indeed, every week, brings forth works of amusement and instruction adapted to every age, as well as for every class of society—when we have such popular volumes as Kirby and Spence's "Introduction to Entomology," "Penny Magazines," and equally cheap Cyclopædias—it seems incredible, to those who have a taste for scientific pursuits, that any one in England should not be better informed concerning the works of the Creation which daily surround us, than to suppose that flies vary in size according to their age, and that consequently the large and small are the old and young of the same species. To assist in dissipating such errors, and to establish truth in their stead, being our great aim, we will introduce the history of the House-fly. There are fifty, perhaps a hundred, different sorts of flies and gnats which annually visit our apartments: I mean regular domestics, for if casual visitors be included the numbers will be quadrupled. Amongst the former are the Green-bottle flies, the Blue-bottle or Flesh-fly, and another very like it called the Larder-fly, bouncing against the windows; then there is the biting House-fly, which interrupts our reveries by stinging the legs and ancles, also the lesser and larger House-flies, alighting on our food and soiling the furniture.

Their economy and transformation being similar, we need only give the history of the last at present. The House-fly, like most other insects, lays eggs, and probably a considerable number; these are deposited in hot and moist dunghills, and probably in putrifying vegetables and refuse in gardens, muck-bins, and similar situations, and hatching into minute maggots of a dirty white and yellow colour, they feed until they arrive at the size of fig. 2, and greatly resemble the gentles which are used for bait in fishing, and which are generally the maggots of the Blue-bottle fly—except that they are totally destitute of the fleshy tubercles which those larvæ have the power of protruding from their bodies to aid their locomotion. When fat and full-fed, they lie dormant a few hours, during which time the skin hardens and becomes an oval cylindrical horny case, of a chesnut or rusty brown colour (fig. 3); and in this the two-winged flies, called Diptera, differ, perhaps, from all the other orders of insects, which cast their skins when they become chrysalides. In this quiescent state they remain from a few days to as many weeks, according to the temperature, many of them, no doubt, sleeping through the winter. Whilst in this state of repose, the recent maggot is undergoing a wonderful transformation within his own skin, which at last opens at one end by a little circular lid, and out creeps the House-fly with its body and six legs, as large as they are at any subsequent period of its life—indeed, the abdomen is often larger, as it is filled with a fluid, which is afterwards discharged; but without this the wings would not expand: for when the fly issues from his tomb, the only part which has to grow is the wings; these are two little crumpled moist objects on each side of its body, like two pockets; its first object, therefore, is, before they dry, to crawl up a wall or straw, when the fluid gravitates or is forced into the nervures or delicate veins of the wings, which expands all the wrinkles, for they are not folds, and at last these organs are stretched out and covered with a delicate transparent but iridescent membrane, and then the little animal is ready for flight.

It is now time to describe the Housefly, which is magnified (fig. 1), the cross lines showing its natural dimensions when the wings are expanded. It is one of the few insects which still bears the name assigned to it by Linnæus, who called it Musca domestica; it is clothed with black hairs and bristles; the antennæ are black, with feathered setæ; the eyes are remote, particularly in the females, and are of a dull or brownish red; the space between them is black, but the face is satiny yellowish white, and a similar line surrounds the eyes; the thorax is bright grey, with four blackish longitudinal lines; the abdomen cinereous or clouded ochreous, with a blackish line down the back, and smaller elongated spots on each side, varying with the light; the belly is ochreous, base of the wings yellowish; the six legs are long, slender, and blackish. The abdomen of the male is of a transparent ochre on the sides, and the apex is rounded; but in the female it is conical, and often of a clouded ash-colour.

A very accurate observer, Mr. R. H. Lewis, says—that this and some other flies "were common in the ship from England to Van Diemen's Land, breeding in the rotten Potatoes, &c. No wonder, therefore, that this fly is so much diffused; and it will probably be difficult to fix its original country. I can state from personal observation that the Musca domestica of Canada, the United States, Cape of Good Hope, and Hobart Town (where they are very numerous), are identically one and the same species with that of England; and from the facility with which it propagates, I think it probable that it is to be found in every part of the world. * To the same genus belongs Musca Cæsar Linn., the Green-bottle fly, † and the Musca vomitoria Linn., the Blue-bottle or Flesh-fly; but another, exceedingly like it, the Larder-fly, is associated with another genus, and is named Anthomyia lardaria; the nervures of the wings are different, as shown in fig. 5, those at fig. 6 being parallel; whereas, in the true Musca, fig. 1, the cells are closed, or nearly so, by oblique nervures. The Lesser house-fly is now a member of the genus Anthomyia also, and is the M. canicularis Linn.; it is very like M. domestica in colour and markings. The biting Housefly, although so like the darker female of M. domestica, is far removed from it, by the structure of its mouth, which is horny and formed for piercing; it is named Stomoxys calcitrans. ‡ —*Ruricola.*

FAMILIAR BOTANY.

Morphology.

"You see one pervading idea, worked out in every portion; no one thing appearing as an after-thought, though perhaps not introduced till a period long subsequent to the first foundation. The true spirit of Gothic architecture is that of living vegetation: it is the expansion of the vitality of the germ; and, where this vitality exists, each addition harmonises as naturally with the portion upon which it is based, as the leaf does when it springs out of the branch, and as the flower does when it blooms amongst the verdure. However the building may spread and fructify, it is still one organic whole; and this is truly a transcendent excellence, which no other production of human art ever acquired."

Thus speaks a clever modern writer, when describing the Cathedral of Cologne; few consider with what truth and justice, as regards the beautiful simile derived from the vegetable world. Let me endeavour to illustrate the Author's meaning, and work out at length an idea rich in admirable truths, pregnant with the true philosophy of Natural History, and having a direct, though perhaps not apparent, relation to some of the commonest facts of Gardening.

In modern times there has sprung up a branch of science named *Morphology*, so called from two Greek words signifying *a talk about form*, the object of which is to show that in all the works of the creation the plan of structure is extremely simple, although the object constructed may be very complicated; that things, the most unlike, owe their want of likeness to peculiar combinations of things similar, or even identical, and not in their original nature distinct; and, in short, that the multitudinous forms with which all nature teems, are so many evidences of the most amazing skill applied by an allwise Creator to the construction of living matter out of a few general and simple parts.

The Mineralogist shows that chalk, Carrara marble, and Iceland spar—peculiar combinations of a kind of air called carbonic acid, and of lime—are the same thing with their particles in different states of cohesion; and that charcoal and the diamond, flint, rock-crystal, the amethyst, and opal, stand in a similar relation to each other. The Chemist finds gum, starch and sugar to be mere compounds of charcoal and water; four so-called elements to be the basis of all the various forms of vegetation; and possibly two elements, each an impalpable air, to constitute all matter. In like manner, in the vegetable kingdom, experience teaches us that, putting aside the common nature of the ultimate elements of matter, all the various organs which decorate a plant, however dissimilar they may be, and notwithstanding the various uses for which they are destined, are in reality mere variations of one common organ, expanded and united in different ways, and appearing under a multitude of distinct forms. All branches of science which treat of these singular facts may be termed Morphology, but that word is chiefly used in speaking of plants and animals.

Among plants those truths are exemplified in so extraordinary a manner, as to have excited doubts in some persons as to their existence. It has seemed to some minds so inconceivable that the scarlet blossom of the Lily should be composed of the same parts as the green foliage that stands below it, or that the succulent fruit of the Peach should be one of the thin leaves of the Peach-tree folded up and altered, that, without attempting to examine the facts on which the doctrines of Morphology depend, they have rashly accused its advocates of Atheism, and proclaimed one of the most wonderful manifestations of Divine power and contrivance with which man is acquainted, a sign of materialism, and a badge of infidelity. If I did not know how often clamour beats down truth, for a time at least, and what influence is exercised over the thoughtless by strong assertion, when it is not contradicted, I should probably have left a demonstration of the facts of Morphology to some other pen; but it seems due to the readers of this Paper to put them in possession of the evidence, and to dispose of the many foolish notions that are prevalent, on the subject. I shall therefore endeavour, during the present season, to bring forward, at short intervals, a complete series of illustrations of the manner in which morphologists support their case. In the meanwhile it may be stated, for the satisfaction of the feeble-minded, that, Linnæus was one of the fathers of these opinions, and no one ever accused that great man of Atheism or infidelity.

It is surprising that those who are shocked at the idea of a leaf being converted into a fruit should never have considered some very common facts with which they can hardly be unacquainted. The following passage from the writings of a modern Swedish authoress may be recommended to their attention until we can resume the subject:—

"The flower appears to us at first as a seed, then a sprout; the sprout becomes a bud, and now the flower unfolds itself. Similar changes are shown us by other objects in nature. See, yonder creeps the despised crawling caterpillar. The hour comes, and the feebleness of death falls upon him; he gathers himself up and weaves the cocoon; this web forms his shroud, while the organs of his new being are already inclosed within him; now the rings appear, the inner powers are struggling now; the change goes forward and decay appears; his ten feet remain upon the old skin, and the new creature lies with its limbs yet unformed. By degrees these come forth in order, but the creature does not awake till all is perfect; now he presses towards the light, and the last change is quickly made. A few minutes and the tender wings become ten times larger than when beneath the death-shroud; they are gifted with an elastic strength, and glitter in every ray of the sun. His whole being is changed; instead of the Grass and leaves for which he was before created, he now sips nectar-dew from the golden cups. Who would perceive in the form of the caterpillar the future butterfly? Who would recognise in both one and the same creature, if observation did not teach it us? And both existences are only one life, and the two beings are one and the same earth, in which the organic circle constantly repeats itself."

What is there in the transformation of a leaf into a flower or fruit more remarkable than this?—*R. E.*

BEES.—No. V.

(Continued from p. 51.)

The Feeding of Bees.—Some springs are so very rainy that Bees cannot gather enough to keep themselves; sometimes rainy weather immediately ensues after swarming; and sometimes a rainy summer hinders Bees from laying in a sufficient store of provisions to keep them alive till spring: on such occasions feeding becomes necessary. The best thing to feed Bees with is loaf-sugar and water, at the rate of a pound of sugar to a pint of water, slightly boiled. Raw sugar and water produces diarrhœa, and is often used in spring; indeed, I have used it in autumn, and saw no bad effects resulting therefrom. Foreign (Russian and Prussian) honey has been used. One gentleman, who had used honey from Dantsic, told me that if it was given to Bees in an unadulterated state (that is, not mixed with sugar), it would poison them; and another told me that his father fed his Bees with Russian honey, and that it was good and safe enough for such a purpose; but I myself never saw it used. Bees will even eat treacle and boiled

* Ent. Trans., v. i. p. lxxx. † Curtis's Brit. Ent., fol. and pl. 349. ‡ Ib., fol. 66d.

Potatoes, if soaked in sugar and water; but I recommend nothing but loaf or refined sugar and water. When I say that it is better than anything else, I of course exclude British honey. Some Bee-keepers use porter or ale instead of water, which is more expensive and no better. Some may object to loaf-sugar because it is dearer than raw; but let me say that it is nearly as cheap, for less serves Bees. Five pounds of honey collected from the flowers of White or Dutch Clover last nearly, if not quite, as long as 7lbs. collected from the blossoms of Heather or Ling—or, as it is sometimes called, Heath. There are various systems of feeding. I will not offer an objection to any; but I would recommend the following:—Turn up the hive, place it against your thigh or your knee, and pour the liquid first on the one side of the combs, and then on the other. If the combs are held at an angle of 45°, the liquid runs into the cells before it reaches the crown of the hive. The Bees soon lick the liquid off themselves. Both in a profitable and speedy point of view this system, I think, surpasses any other for autumn feeding; for one man, in one day, could give 50 hives 5 lbs. each; that is to say, five or six doses. If Bees are fed every day they do not lay by much; it causes them to fly about a great deal; hence it is dangerous to feed in cold weather. Where time is no object, tin troughs and cisterns ought to be used in spring. In feeding swarms that have not worked their combs down to the boards, soup or broth-plates are used. A few straws are cut and placed on the sugar and water, to facilitate its being taken up, and to prevent the Bees from drowning themselves therein. The Bees form or make ladders of themselves, which reach from the body of the swarms to the centre of the plates. These ladders save many Bees the trouble of going round about by the sides of their hives. It is advisable to feed young swarms in rainy weather, whether they are needful or not, for Bees, at the swarming season, make combs very fast from sugar or treacle, wax being a secretion of Bees and not of plants. If young swarms are not attended to during unfavourable weather, their numbers decrease instead of increase, because they have scarcely any comb to breed in.

Upon the immuring of Bees in winter I did not intend to offer a remark; but I wrote to Carluke in order to learn if any one there had buried his Bees in winter; at the same time I desired the person whom I wrote to, to bury two of his hives or stocks—one without food and another with a sufficient quantity to keep the Bees alive. In answer to my letter, my correspondent informs me that "no one here has tried the burying system, and I dare say never shall; for a man in Cambusnethan (the adjoining parish) buried one with as much honey in it as would have kept the Bees alive above ground till the spring: when he took it out all the honey was eaten and the Bees were dead." This quotation teaches us that Bees live under the ground when they have food, but die when they have none—and that they eat more under than above the ground. The first and second of these are in accordance with common sense, and the last with philosophy. If Bees live under the ground without food during the months of October, November, December, and January, it is but fair to infer that they will live four weeks in summer likewise! We are open to conviction; but it will be a hard matter to make us believe this.—*A. Pettigrew, Wrotham Park, Middlesex.*

(*To be continued.*)

DURABILITY OF OAK TIMBER, FELLED WITH THE BARK ON IN WINTER.

"I send you two specimens of Oak bark, with their dates, taken from beams in old buildings, lately taken down in this neighbourhood, which prove beyond doubt that winter is the best time for felling Oak timber, when durability is required.

No. 1 was taken from a beam in an old house in Llanymynech, in the county of Salop; the date cut in a stones on which one end of it rested is 1316, which, subtracted from 1843, makes its age 527 years. The timber under the bark is quite hard and sound, as may be imagined from the state of the bark, which appears as sound, fresh, and heavy, as if it had been there only a short time; the beam had been covered over thickly with lath and plaster. No. 2 was obtained from a beam in an old building in Oswestry that was taken down; the date 1035 was cut in the timber in two or three places; this, subtracted from 1843, makes its age 808 years. The bark was quite fresh and sound, and the timber under it was the same; the ends of the beams, having been over a doorway, and exposed to the weather, were decaying; but the other parts were sound.

This incontestably proves that Oak timber is most durable when felled with the bark on: whether our forefathers knew this by experience, or merely did so by chance, the bark at those times being possibly of little or no value, is more than I can affirm. The fact of its durability when found in this way has been further confirmed by the evidence of persons who have had much experience in working up timber from old buildings. At another place, near Oswestry, was Oak timber found with bark on, nearly 900 years old. It was reported to be quite sound by the person who worked it up for fresh purposes.

There was lately sold, in a neighbouring Welsh county, to a Dock Company at Liverpool, two Oak trees, to be felled with the bark on, in winter, purposely for gates to docks, for 6*s.* 6*d.* per foot; one tree contained 120 feet, and the other 125 feet of timber.

I am informed that coach-makers, who require hard, durable timber, purchase it while standing, and have it felled in winter, sacrificing the value of the bark. The white or sap-wood of the Oak will begin to decay in a very short time when pelled and felled in spring, whereas it has been proved by experience that it is hard and sound when felled with the bark on, in winter.

From these facts there appears little, if any doubt, that Oak timber felled with the bark on is the most durable. —*W. Billington.*

[The specimens sent by Mr. B. are perfectly sound, and appear to belong to trees that have never been even squared.]

Home Correspondence.

Border Carnations and Picotees.—For Carnations I would recommend Hoyle's Duke of Leeds, and Ely's Dragoon, S. B.; Gregory's Alfred, and Ely's Duke of Bedford, C. B.; Ely's Bright Venus, and Orson's Rob Roy, S. F.; Ely's Lady Ely, Hogg's Lady Stanley, Chadwick's Lucette, R. F.; Elliot's British Queen, P. F. Hoyle's Duke of Leeds, when run, is more admired by ladies here than when clean—the petals are apparently thicker and more velvetty in the run-flowers, and their colour very rich and dark. Is this alteration in substance of petal owing to the effect of light? This flower is increased readily by pipings. I have observed that pipings of it in a glass with others are often the first rooted. Dragoon is easily piped, but layers of it will flag unless immediately placed in the shade. Duke of Bedford and Bright Venus seldom run with me; the other sorts will, but in a border this is no objection. They are all good growers, easily propagated, and their price does not exceed, on the average, one shilling per pair. Maud's Rowton, scarlet flake, when run, is a beautiful object in the border; in the clear flowers the white is not good. Ely's Tree Carnation, scarlet flake, throws up a tall flower-stalk, from the sides of which spring numerous shoots, all which can be piped. The calyx is often "Wheat-ear." I have seen this variety look very interesting and showy when blooming in a greenhouse in winter. The following Picotees are suitable for a border. Red—Ely's Criterion, Hardy's Royal Briton, Woolard's Miss Bacon, Hirst's Admiral Sotheron, Banton's Mazeppa. Purple—Lee's Lady Wildman, Pullen's Incomparable, and Lady Peel, Birtle's Lady Fair, Kirtland's Victoria, Jackson's Delight. Rose—Giddin's Hemingford Beauty, Syke's Eliza, Wilson's Fanny Irby. Yellow—Martin's Victoria, Hamburg Yellow. All these are cheap, showy, and readily increased.—*O.*

Pits.—Our correspondent "Economist," who some time ago requested Mr. Paxton's opinion respecting the most economical mode of constructing a range of pits for general purposes, such as for growing Pines, Cucumbers, Melons, &c., also Pelargoniums, Fuchsias, Calceolarias, Heaths, and other greenhouse-plants, is answered in the following:—

Fig. 1.—Longitudinal Section.

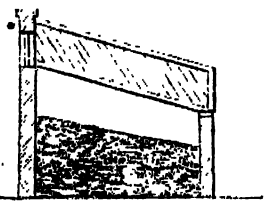


Fig. 2.—Transverse Section.—Scale ½ of an inch to a foot.

"The best method of building pits is to construct them of nine-inch brick on bed, and the best mode of heating them is by Rogers' Conical Boiler. In the present case, "Economist" may build a pit 78 feet long inside and 7 feet wide. Cover the pit with a ridge and furrow roof, making the space from the ground in front of the pit to the valley-rafter 3 feet 6 inches, and the back wall below the rafter 5 feet 6 inches—see section across the pit, *fig.* 2. Divide the whole length into four compartments for growing the different sorts of plants, by 4½ inch brick-on-bed walls. Divide the whole length of the ridge and furrow-roof into 12 bays, having a ventilator in the angle of each pediment, as at *d d*, *fig.* 1. Now, to get to the plants, each light is hinged at the valley-rafter, and fastened with a thumb-button at the ridge-rafter. By referring to *fig.* 1, it will be seen that the light or frame leaves the ridge-rafter at *a* in the direction of *b*, and lies flat upon the next light at *c*. Each light may be opened in this way, so that a workman may get to any part of the pit."—*Joseph Paxton.*

Charcoal.—Last year I potted two standard Hydrangeas in 16 sized pots, with two-thirds turfy loam, and one-third sifted charcoal; the drainage, which was three inches deep, I formed of coarse pieces of charcoal: when the plants bloomed, I found the colour of the flowers to be a beautiful bright blue, and so they continued to flower the whole of the season. Every plant seems to delight in charcoal; since I have laid charcoal merely on the surface of the mould, round the stems of many of my large Orange and Lemon trees, the alteration has been very striking; the foliage assuming a dark rich hue, and the plants being altogether most luxuriant. It is my opinion that large beds of blue Hydrangeas might be easily obtained by the above treatment.—*J. L. Snow, Swinton Gardens.*

Charcoal.—In the Forest of Dean I observed that the Charcoal "hearths or floors" soon became spontaneously covered with seedling Willows, of a very vigorous growth. These seedlings made their appearance in about a year after the fires, and I do not recollect any other kind of seed germinating there except the Willows. Some time ago I saw in the *Chronicle* observations on a kind of shale as a manure. Now in this forest is a kind of blue shale over the stratum of coal, this after being exposed to the atmosphere for some time crumbles down like shell marl. Mounds round some old coal-pits composed of this material were planted with Oaks, which became the most vigorous of any in the forest, and were covered with healthy dark-green shining leaves. The coal shale is a valuable manure and would be useful to farmers, particularly upon light sandy heath and bog soils, and in localities where it abounds the proprietors of coal-works might profit by it.—*W. Billington, Oswestry, Salop.*

Curl in Potatoes.—Mr. Barnes, at p. 424 of the "Gardeners' Magazine," mentions that the disease known by the name of "curl" is chiefly occasioned by the use of seed Potatoes not fully ripened. Mr. Dixon has made the same observation in his treatise on that disease. This, however, will not suffice to account for it: for how is it that the "curl" does not affect Potatoes on some particular soils, even when little attention has been paid to the quality of the seed; while on other soils it attacks them, however well ripened the seed-Potatoes might have been? The former happens in moorland districts; the latter on light rich soil near Edinburgh. In order to prevent "curl," I have known gardeners at the latter place procure seed from their friends in the Moorlands. If they did not continue to do this, the "curl" would appear the second or third year. This supports the opinion that the disease is occasioned in some measure by the richness of the soil, or rather by its having been long under cultivation. It has been imagined to be owing to the tubers decaying in the soil; but this does not explain why some soils affect them and not others. Decayed tops make a good and useful manure for a succeeding crop of the same kind; why then should decayed roots be prejudicial? Mr. Barnes speaks of "curl" being caused by the over-ripeness of seed-Potatoes, and yet says that—"all Potatoes that are meant for seed should be ripe and hardened by the sun and air." He further observes that "all kinds of seed may be over-ripe—that is, lose a considerable quantity of its properties." He complains of the plan of planting Potatoes late, without stating what has generally led to it. He must be aware that when the late kinds of Potatoes are planted early, for instance, about the latter part of May, or 1st of June, especially on light land, they are apt to make what is called a second growth. To prevent this, the Norfolk farmers defer planting their Potatoes until the 1st of June, in order that the tubers may not be prematurely ripened by the Midsummer drought; otherwise they would send forth many more little Potatoes, to the serious injury of the main crop. In this case the first-formed Potatoes are hard and fibrous, and the small ones produced from them, and attached to them by shoots, are small, and fit only for pigs.—*J. Wighton, Cossey Gardens.*

Pine Apples.—Although I have not been engaged in Pine growing for nearly five years, I am much interested in the culture of that delicious fruit. Mr. Murray says that he "adopts the large-shift system to a much greater extent than is recommended by Mr. Glendinning, and proposes to carry it still farther next year." In a leader it is stated "that this is a certain precursor of getting rid of potting altogether." I quite agree with this remark, and have little doubt but that the natural system, (as it may be termed,) in time, will be generally practised. I am the more satisfied of this from having had some experience in the growing of Pines without pots for several years, and shall here give you a short account of my proceedings and success. About ten years ago my employer caused two Pine-houses to be built; the pit for the Pines was about two feet deep, with a hot-air chamber below heated by a flue. Being fully aware that a dry heat would not answer, I had large pans placed along the top of the flue to be kept filled with water, and had also water dashed along the floor of the chamber every morning. There were ventilators from the outside to admit cold air into the lower part of the chamber, and also ventilators in front and back of the pit, connected with the hot-air chamber, so as to admit the hot air into the house when required. In March I prepared my bed for the Pines and turned out one-year-old plants; they had been growing the first 5 months without pots in an old Pine pit; they were afterwards potted into rather a large shift, where they remained until I turned them out into the new pit in March following. They grew very strong, and a few began to show fruit about the middle of May, and continued doing so up to the middle of July, when all had shown fruit; they swelled off very well, and produced fruit from 3lbs. to 5 lbs. avoirdupois; they chiefly consisted of the Queen, Globe, Enville, Jamaica, Otaheite, and Montserrat. I continued the same plan the year following and with the same success, with the exception of a few of the Providence that I planted amongst them; these did not fruit until the succeeding year, when they produced fruit double the size of the others. After this I was determined to try the natural system entirely in one of the houses. In March I planted strong suckers of the above-mentioned Pines, alternately with the Providence, the former to be fruited off the second year. I cleared the plants away as they ripened, to make room for the Providence, which require a year longer to produce fine fruit. I succeeded in this equally well; the smaller sorts fruited the second year and were cleared away; the Providence grew very strong and began to show fruit about the beginning of April. The third year, when I left my situation, I was informed that they produced very fine fruit, weighing from 8 lbs. to 11 lbs. From the experience I have had of this system I have not the least doubt of its success; and had I to grow Pines again, I have so high an opinion of it that I should never grow a Pine in a pot. Many Pine-growers imagine that there is a difficulty in getting them to fruit, but I found

none, no more than in the pot-culture. It is attended with little trouble; the saving of labour is very great, and there is also a saving in pots. From the time the suckers were planted to the time the fruit was cut the plants were never lifted, but a few of the lower leaves were removed and a little of the top soil was taken away and filled up again with fresh soil; this was done about March and again in September. Between these times I loosened the surface-soil occasionally.—*R. M., a Landscape Gardener.*

The Love Bird.—A correspondent wishes to be informed if the Love-bird (Agapornis pullaria) has been known to breed in this country; as, he says, a few years since three eggs were laid by a cage bird belonging to a lady at Cambridge who had kept these birds for a considerable period.

Larch Trees.—My attention has been called to a proposition which your correspondent, Mr. W. Billington, states interrogatively as to the propriety of felling Larch and other resinous trees in the early part of summer, on the ground that at that period "there is more of the resinous fluid afloat, or at least it is more regularly dispersed in the wood." I have frequently heard this idea broached, and am glad of an opportunity of contradicting it from experiment, as I have always done from theory, it being at variance with all correct principles. Every physiologist must be aware that the "resinous fluid" is a product of the plant itself, after the elaboration of the sap in the leaf, and, owing its existence to that elaboration, can only be met with in a descending or half-deposited state. We know that the first sap which rises in the returning summer unites with a portion of this deposit, causing the germination of the earliest buds; but in so doing, it only dilutes, not increases, the quantity of the last year's manufacture, so to call it; and by so doing only loads the timber with a quantity of water, the gradual evaporation of which after the timber is felled produces sun-cracks, and an evident predisposition to decay. If your correspondent will try the experiment, he will soon be satisfied of the error of this notion—which has become almost a popular one—that resinous trees should be felled in summer. Let a few Larch be cut down in March, and an equal weight cut in the following June or July (and it is by this that I have proved it), and let them be weighed against each other again, after lying in the timber-yard a twelvemonth; he will find that the summer-felled trees have lost weight against the others to a very considerable degree, besides the cracking and warping exhibited by all summer-felled timber. In fact, the sooner this opinion is exploded the better; for it arises from an entire want of acquaintance with the distinction between the rising sap, which (for our purposes at least) is little else than water; and the elaborated juice, or cambium, of the plant, which is, of course, most plentiful in the stem just at or before the fall of the leaf, and most effectually consolidated and dispersed in the timber in the winter. With regard to the latter part of the proposition, that it is at that period, viz., in June, "more regularly dispersed in the wood," the supposition is purely conjectural and empirical. Nothing can be more perfect or more equable than the disposition of its elaborated juice, which the plant itself has made; and the rising sap rather disturbs and deranges this disposition; of course, for an obvious and active purpose; which, however, being unfulfilled at the time of felling the tree, it lies in a state of arrested vegetable energy, so to speak, extremely favourable to early decay. Whilst I am on this subject, I am anxious to say one word on the pruning of resinous trees, about which such conflicting opinions are observed in the works on Arboriculture; some advising the excision of the bottom tier of lateral branches each year, but the generality forbidding all pruning whatever, and advocating their being allowed to prune each other by proximity. Like the umpire in the Fable of the Camsleon, I am obliged to say, "both are wrong." If one tier be taken off each year, it will be sometimes too much, sometimes too little, according to the growth and peculiarity of each tree; if they be allowed to prune each other, they leave dead snags sticking out in the stem, which the descending sap is obliged to surround, but which if cut off close to the stem it would have overlapped, and preserved from decay; and completing the annularity of that year's layer of new wood, would have made the timber stronger and more regular. Pruning is a matter not of rigid rules, but of principle. Let the pruner look at the internode above and below the branch in question; if the one below is considerably larger in girth than the one above, then the branch may come away with advantage, provided the plant be vigorous; and in the following year he will find the proportion between those two internodes of the stem more equable. If the two, or even three, bottom tiers have a disproportionately thin internode above them, and the stem be large and tolerably even in size between and below them, then those two or three tiers may all come away. But if the stem preserve a very regular proportion all the way up, then the tiers should only be taken off one by one, beginning at the bottom, as they begin to cease growing. If one branch of a tier, whether high or low in the tree, be exuberant, let a part of it be taken off. The best time to prune the resinous trees is either in October—with the view of the wound being covered by the turpentine before the frosts come,—or in March after they are gone, and a month or six weeks before the spring sap begins to rise, that the surface of the wound may have time to harden so as to destroy the elasticity of the mouths of the sap-vessels, and prevent the escape of the rising sap.—*C. Wren Hoskyns, Wroxhall.*

Domestic Yeast.—Persons who are in the habit of making their own bread can easily manufacture their own yeast by attending to the following directions. Boil one pound of good flour, a quarter of a pound of brown sugar, and a little salt, in two gallons of water for an hour when milk-warm bottle it and cork it close, and it will be fit for use in 24 hours. One pound of this yeast will make 18 lbs. of bread.—*J. Mc I., Hillsborough.*

Rats.—The great increase of rats in the present day is partly owing to trapping the domestic cat close to the labourer's cottage. I am, myself, no very great friend to the feline race; indeed, at one time, no animal ever raised the bristles of my temper half so frequently as poor puss; but since I began to place cheap netting over my newly-sown flower-beds, Tom and I have been on pretty good terms. Nevertheless, villages are ransacked, and in whichever direction you ride the sixpenny prize is too frequently exposed upon some wall or paling. Here we see the pied, the sable, the tortoiseshell, and the old maid's tabby, arranged as trophies of victory. What a deprivation must it be to the cottager on his return home from labour to miss the greeting of puss! how annoyed must he feel at no longer hearing his favourite purring round his legs! Many of our peasantry (thanks to an increasing love of gardening, and less frequent calls upon John Barleycorn) are now enabled to keep a pig; such at least was the case in the neighbourhood in which I sojourned during the past summer. The sty soon becomes infested with the above-mentioned vermin, which partake of the food given to the grunters, and if not destroyed they soon betake themselves to the hedges and ditch-banks in large hordes. We now see fields completely overrun by rats, and burrowed more like the works of rabbits than those whiskered gentry. The sportsman will doubtless argue that the cat, if once given to ramble, kills a large quantity of game; but I much doubt if the cat really destroys game equal to the rat, particularly in the breeding season; for the latter not only feeds upon the young birds, but also on the eggs of partridges and pheasants. These observations have been elicited by seeing several accounts in the *Chronicle* of the damage occasioned by rats; such statements at first appear almost incredible, but unfortunately there can be no doubt of their truth. I myself saw, only a few months back, hundreds of rats slaughtered in one field alone.—*A Quiet Observer.*

Polyanthus.—I found seedlings from Alexander very variable and uncertain. Those from Lord Rancliff generally resembled the parent, and there were many pretty varieties, but with small flowers. Those from Tantarara were like the parent. From Collier's Princess Royal I had round flowers with many petals; but by far the best were raised from fine-eyed seedlings, impregnated with Buck's George IV., Rancliff, or other good sorts. Among these I had varieties of all shades; and latterly I have saved seed from the fine-eyed ones only—propagating the best for that purpose, and nipping off the flowers from the named sorts when I have got their pollen. Loudon and others have said that this plant is much hardier than the Auricula: the very contrary is the fact; for in 1838 I saw both in a frame—of which many squares were out: the Auriculas all survived, and seemed little worse; the Polyanthuses were all killed. Over-potting is very bad for them; a little heat in early spring seems to help them to root; they should have timely attention in autumn to get them established early, and a situation kept regularly moist by shade and shelter from all drying winds.—*O.*

Dutch Clover.—The sudden appearance of Clover in pastures after some particular top-dressing, or in certain moors after the ling has been burnt, has often excited the surprise of observers, though perhaps without inducing them to make any accurate investigation of the circumstances under which it is produced; and it is probable that, in some cases, there has not been an acute discrimination of species. Observations by some competent person on this point would certainly not be without interest, and might lead to more important results than might at first be anticipated, both in a scientific and economical point of view. A still more curious and inexplicable instance of the sudden occurrence of a large natural crop of White Clover is that which so commonly takes place when large districts, as on the Lincolnshire coast, are rescued from the sea by embankments, and fertilized by the admission of the tide after the embankment has been completed, until the tract of country is in a proper state for cultivation. Some one conveniently situated for such observations, with a very slender botanical knowledge, but with a turn for patient and accurate investigation, would, by commencing from the moment of the final exclusion of the tide, most probably be able to clear up this very perplexing matter. As regards the appearance of Clover in pasture lands, there is by no means the same difficulty; for, not only will the seeds lie dormant for years where they are out of the influence of air from the presence of a thick vegetation above them, but it is very probable that in certain cases they may be propagated by the little tubers which are so general on the roots of Clovers, Vetches, and many other leguminous plants. These, indeed, in general appear to be mere reservoirs of nutritive matter, for they often run through their phases of developement very rapidly; but in other cases it is far from improbable that, when they are not demanded by the exigencies of the plant, they may be capable of reproducing it, as we know that such bodies may lie dormant for years. Everyone must have observed, after the periodical felling of woods, what a quantity of herbaceous plants appear, of which there has not been a trace for years, merely from the clearing of the surface of the soil from its thick coat of underwood. And this is not only the case with plants which spring from seed, but with others; as Orchidaceæ, which spring more generally from tubers. In certain woods which abound with the Fly Orchis, just after the periodical felling, not a trace is to be found for years after the underwood has once re-established itself. A very curious instance of the appearance of a plant hitherto unknown in the neighbourhood has lately fallen within my observation. An old tree was felled in a wild part of Rockingham Forest, and in the centre of the old stock, a single individual of Cynoglossum sylvaticum appeared, a plant which I have never before observed in this district, though acquainted with it from my infancy. A large crop has sprung up from this individual, and it is probable that it is now completely established. These and many other curious facts of a similar nature may occasionally excite our surprise; but it seems most unnecessary to have recourse to any notions so wild as those of spontaneous generation. The circumstance of the appearance of a species of Acarus during the course of certain chemical experiments instituted by Mr. Crosse, was laid before the French Academy, and they were, I believe, unanimously considered quite unworthy of attention as connected with the question of spontaneous generation. In the instances which have given rise to the present observations, there ought to be some pretence at investigation before explanations of such a nature be adverted to. For my own part, I should not think the appearance of a flock of sheep by spontaneous generation in the Lincolnshire marshes a matter at all more marvellous than that of a crop of Clover springing up without any pre-existent germs, for the adaptation of the several organs to the purposes for which the object was created does not show the wisdom and power of the Creator less in one case than the other.—*M. T. Berkeley.*

Gold of Pleasure.—An oil is expressed from the seeds. In France, brooms somewhat resembling our carpet-brooms, are made of the dry plant after the seeds have been threshed out.—*M. T. B.*

Ash-leaved Kidney Potatoes.—I bastard trench a piece of rich light sandy ground, about 18 ins. deep, and break it well with a spade. At the bottom of each trench is spread some half-decomposed horse-dung, about four inches deep, and on this I plant the sets whole, cutting a small piece of the narrow end off, as I consider it is useless, and placing them upright, the ground is planted as the trenching proceeds; the tubers are laid in lines fully nine inches deep and nine inches apart in the rows, which are 18 inches from each other. I cover the surface of the ground for about three inches deep with dung, similar to that which is put into the trench. They receive one moulding up when the Potatoes are about six inches high; a little damaged salt is mixed with the soil, which causes the Potatoes to be well flavoured. By adopting this plan an excellent crop may be produced early in June if the tubers are planted between the 25th and 30th of January. In taking up the crop select the best ripened ones, and let them be thoroughly dried in the sun until they become shrivelled; these will always come earliest. —*Anonymous.*

Reviews.

The Botany of the Voyage of H.M.S. Sulphur. Edited by R. B. Hinds, Esq.; the Botanical descriptions by George Bentham, Esq. 4to. Part I. Smith, Elder, and Co.

The voyage of the Sulphur occupied a period of six years, during which time the south-east of South America, the whole of the west coast of that continent, some of the islands in the Indian Archipelago, and eventually the coast of China were visited. Mr. Hinds, who was the surgeon of the expedition, was a zealous naturalist, and lost no opportunity of forming collections, especially in Conchology and Botany. His Herbarium was placed in the hands of Mr. Bentham, and the new plants which it contained are to be published in the present work, under the authority of the Lords of the Admiralty, the Botanical descriptions being written by Mr. Bentham, and the general observations by Mr. Hinds, whose attention was particularly turned, during the whole voyage, to Botanical geography.

The Number before us contains the commencement of the Californian Flora, and is illustrated by 10 lithographic plates of remarkable plants of merit. Mr. Hinds gives a graphic account of the general nature of the vegetation, and especially of the Russian settlement of Sitka, which we must extract.

"The number of rainy days in the year is very great, and at Sitka only 37 really fine clear days were recorded throughout this period. At this Russian settlement some extended observations gave the mean temperature of the year as 45° 5′, and the range from 2° 3′ to 81° 9′. The whole country is bold and mountainous, intersected by deep and moist valleys, and is everywhere covered by a gloomy forest of Spruce. These vast forests offer a scene which powerfully arrests attention. The trees are often of enormous dimensions; stretching upwards, with scarcely a branch, to where the eye almost fails to follow them, with enormous trunks, very deceptive till brought within the scope of our experience by means of the tape-line; beneath, a most luxuriant undergrowth everywhere abounds, and has an exuberance and charm about it which is rarely supposed to be possible beyond the tropics. But over these the influence of the moist climate is unceasing. It most probably hurries through a rapid existence the more lowly shrubs, and its effect on the trees is very marked. None are seen to attain any great age, that is, none have that appearance; but when the vigour of life is past, they rapidly yield to the constant influence of the moist atmosphere, soil, and investment of Mosses and Lichens, and soon fall to the ground, which in some places they occupy in great numbers. But as is everywhere observable where the climate is uniform, the variety in species is not great; and some will occur with multitudes of individuals covering a very large space.

The account of Upper California is not less interesting.

"It was late in the autumn of 1837, when an expedition up the Rio Sacramento penetrated from San Fran-

class some distance into the interior. The country exhibited a vast plain, rich in a deep soil, and subject to periodical submersion. Occasional clumps of fine Oaks and Planes imparted an appearance of park-land. They were already shedding their leaves; a small Grape was very abundant on the banks, and we sometimes obtained a dessert from the fruit of a Juglans. We had scarcely returned, when a storm covered the maritime range of hills with snow; and this set the final seal on the year's vegetation. On quitting the coast for the interior, we exchanged the evergreen Oaks for deciduous species. The latter grow to fine trees, with wood of great specific gravity. But the natives have a very pernicious practice of lighting their fires at the bases; and as they naturally select the largest, it was really a sorrowful sight to behold numbers of the finest trees thus prematurely and wantonly destroyed. And it is not a country where wood is superabundant; for no sooner is the Oregon crossed than the Spruce forests disappear, and the prevailing trees are Oaks, which towards the South become gradually less abundant."

From this account it will be at once perceived that Mr. Hinds' work is worthy the support which it receives from the British Government. We trust that the same liberal assistance will be granted to Dr. Joseph Hooker and his ample materials for an account of the Botany of the late antarctic voyage of the Erebus.

It was very laudable in this officer to take upon himself duties to which he was not liable, and the Botanical world owes him a debt of gratitude for his meritorious exertions. The public, however, has a right to expect that those collections of plants which were formed at the public expense, and which are now supposed to be buried in the British Museum, should be also made use of. We trust that the Lords of the Admiralty will take measures to rescue them from their lurking-place, and cause them to be placed in the hands of Mr. Bentham, than whom it is impossible to find a Botanist better qualified for their examination. The collections to which we allude were formed by Mr. Barclay, and we believe Mr. Sinclair also, the former of whom was sent out at the public expense and the forming such collections was part of his duty.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

STATICE BYTHOPHYLLA. Rasp-leaved Shrubby Sea Lavender. (*Hardy Greenhouse Plant.*) Plumbagineæ. Pentandria Pentagynia.—This is a very beautiful species of Statice, and easily cultivated as a hardy greenhouse plant; but of its history I regret to say I can get no satisfactory information. The Royal Gardens at Kew are indebted for the possession of it to Mr. Low, of Clapton; and it exists in several gardens under the name of S. Dicksoniana. Mr. Mackay, of Dublin, informs me that he raised it from South African seeds, given him by Mr. Harvey, and that he understood it to have come from Port Natal. But I find nothing of the kind among my own specimens from that part of the country, and although Mr. Harvey is aware that he brought to Mr. Mackay seed from the Cape of Good Hope, he had no reason to suppose that the collection contained any from so distant a region as Port Natal. Respecting its native country and introduction we must still remain in doubt; but there can be no question about the beauty of the species, or its merits as a standard plant for cultivation.—*Curtis's Botanical Magazine.*

LUPINUS ARVENSIS. Field Peruvian Lupine. (*Half-hardy Biennial.*) Leguminosæ. Diadelphia Decandria.—This is a gay little plant, forming one more addition to the large genus Lupinus. The flowers are rich bright lilac, enlivened by a yellow spot. In number the leaflets vary from 5 to 9. The seeds, by which Lupines may be distinguished more accurately than by the ordinary marks employed by Botanists, are oblong, smooth, and mottled with grey of different tints. It is a half-hardy biennial, growing from one to two feet high, and flowering a great part of the summer and autumn. Like other Lupines it requires a strong rich soil; and, although a half-shrubby biennial, is best treated as an annual. The seeds should be sown about the beginning of March, in pans filled with a loamy soil, and when large enough should be potted, placing three plants in a small pot; afterwards, when the danger of the late spring-frosts is over, they may be planted out in the open border. The seeds may also be sown in the open border about the middle of April, but then the plants flower much later, and are never so fine as when treated as above stated. It was found growing in corn fields near Loxa, in Peru, by Mr. Hartweg, and flowered in the garden of the Horticultural Society in the course of last autumn.—*Botanical Repaster.*

TURNÆA LOBATA. Lobed Turnæa. (*Stove Perennial.*) Meliaceæ. Monœcephia Decandria.—This very rare Stove-plant flowered at Chiswick House last July. His Grace the Duke of Devonshire received it from Mr. Whitfield, who collected it in Sierra Leone. The flowers have much the appearance of those of the Orange, but have no smell. The nearest affinity of this plant is evidently with the T. heterophylla of Smith, a species from the same country, and apparently very like it. But Mr. Bennett, in his revision of the genus in Horsfield's "Plantæ Javanicæ," p. 164, places T. heterophylla in a section, having from two to twenty cells to the ovary; this, however, has most certainly only five cells with two ovules in each.—*Botanical Register.*

GARDEN MEMORANDA.

Royal Botanic Garden, Regent's Park.—Several structures for plants have lately been erected here. A span-roofed house about 42 feet long and 16 wide has recently been put up; this is in two divisions, one of which is chiefly devoted to the culture of Orchidaceæ, the other is filled with Ferns. Several species of the former were in bloom; among them was a conspicuous and well-grown specimen of Phaius grandiflorus, and a plant of the pretty purple-flowered Bletia verecunda; Sobralia sessilis was just coming into bloom, being the fourth time of flowering this season. In this house was the old Stanhopea grandiflora, producing a fine spike of flowers; this, as well as several other plants, was growing in a basket that tapered to a point at the bottom, something like an inverted cone. These baskets are made of pieces of Hazel fastened round a common centre at the bottom, and radiate outward towards the top. The principal advantages of this shape are, that the flower-stems of Stanhopeas and others that bloom in the same way readily pass through to the outside, and any drip, being always from the point of the basket, can be easily prevented from falling on other plants. A specimen of the larger variety of Maxillaria aromatica was particularly remarkable, on account of its bright orange flowers and agreeable fragrance. Here was also a case filled with plants that had lately been imported from Jamaica. Among them was said to be a species of Ipomœa, resembling in appearance I. Horsfalliæ, which we were informed grows abundantly in the woods in Jamaica. There was also in the same case a Podocarpus, a tree remarkable for the beauty of its wood. This house is heated by hot water in iron pipes. Near it were several ranges of pits; one of them, heated by hot water, was filled with Greenhouse plants, among which were good specimens of Heaths and Epacrises. Passing through a second span-roofed house, 64 feet long and 16 wide, which was filled with half-hardy plants for bedding out in spring, we entered an old stove near it, which contained a few Cacti, and a collection of other plants, along with two bulbs of Ornithogalum revolutum, being part of a large importation of Cape bulbs. In the American garden was a bed of Andromeda floribunda, covered with flower-buds; this about April and May will be a sheet of white bloom. Here were also several plants of Rhododendron Russellianum; this scarlet variety is perfectly hardy; but they had mats thrown round them to preserve their foliage: the Rhododendrons are intermixed with Ledums, Vacciniums, Heaths, Andromedas, &c. Extensive additions, Mr. Marnock informed us, are soon to be made to the general collection, and also to the Medical garden.

The Naturalist's Corner.

Virgil on Grafting, &c.—It seems impossible not to observe the beautiful manner in which Virgil has described the ingrafting and inoculating of trees, in his Second Georgic. The variety of expression which he has used in speaking of the different sorts of ingrafted trees, and the various epithets he bestows on them, render the passage exceedingly delightful. The Arbute is distinguished by its ruggedness; the Plane by its barren shade; and the Pear by its snowy blossoms. It would have become a prose writer simply to have said, that any scion may be ingrafted on any stock; but a poet must add beauty to his instructions, and convey the plainest precepts in the most agreeable manner. Thus, Virgil, after he has said that Walnuts are ingrafted on Arbutes, Apples on Planes, and Beeches on Chesnuts, adorns the wild Ash with the fine blossoms of the Pear; and, instead of barely telling us that Oaks may be ingrafted on Elms, he represents the swine crunching Acorns under Elms, than which nothing can be more poetical. At the close of the passage, he gives life and sense to his ingrafted trees, making them wonder at the unknown leaves and fruits with which they are loaded.—*Professor Martyn.* [All this may be very well for a poet, but it would have been none the worse if there had been a little common sense it it.]

Manchineel.—The fruit and the juice of this tree (*Hippomane mancinella*) are exceedingly acrid, and the latter was at one time made use of by the French colonists in America, for the purpose of inflicting a most barbarous torture upon their slaves. The scourges with which they lashed those unfortunate creatures were prepared by being steeped in the juice of Manchineel, and thus every blow inflicted caused the same agony as if the scourge had been red-hot iron.

Condensation of Carbonic Acid by Charcoal.—The cells of wood-charcoal have a diameter of about $\frac{1}{24}$th of an inch, and if a cubic inch consisted entirely of cells, their united surface would amount to 100 square feet. By experiment it can be shown that the cells constitute $\frac{3}{4}$ths of the whole cubic contents of the charcoal; and allowing for the space occupied by the charcoal, the actual surface of the cells will be about 75 square feet. When charcoal is plunged into carbonic acid gas, it absorbs into its cells no less than 56 times their cubic contents at the ordinary temperature and pressure, and consequently the gas is condensed to 56 atmospheres. But according to the experiments of Addami, carbonic acid liquefies under a pressure of 36.7 atmospheres, and we are hence compelled to conclude that above one-third of the carbonic acid which is condensed on the walls of the cells is in the liquid state.—*Mitscherlich, in Polytechnic Magazine.*

Elm-trees upon the Boulevards of Paris.—For many years these beautiful trees have been suffering, and it was supposed that this was owing to the attacks of the Scolytus destructor. There is, however, now some reason to suppose that it has arisen from the too great proximity of gas-pipes. On opening one of these, it gave out an exceedingly offensive smell; and plants of Wheat, Barley, &c. planted in the soil surrounding the pipe, soon ceased to grow. The roots of the trees in the soil were blackened, and gave out the odour of the gas, which was very offensive.—*Bot. Zeit.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

Any new plant that flowers in winter is double valuable. Clerodendron splendens, Centradenia rosea, and Manettia bicolor are of this class; the Manettia requires less heat than the other two; they will do well in an intermediate stove, and flower freely in a conservatory with 45° of heat. Dendrobiums that have had their shoots well ripened last autumn will soon be beginning to bloom; some of them might now be forced, and others removed to a cool place, and kept dry, in order to prolong their flowering season. Maxillaria aromatica ought to be grown largely for forcing; it is one of the easiest to cultivate. A few Stanhopeas might also now be forced. All of these plants that have been kept dry through the winter should be plunged in tepid water, to soak the moss or peat, &c. in which they are grown, preparatory to regular watering. It is yet too soon to encourage plants in general to grow; many would be benefited by a layer of fresh soil or top-dressing; give large portions of air on fine sunny days.

Conservatory.—Established plants here should about this time have the mould well stirred on the top of the pots. The surface of the border should now be removed altogether, the soil stirred with a fork a few inches deep, and a layer of fresh earth laid on; more air should be given for the first week after this operation, to sweeten the house. Fast-growing climbers that exhaust the soil in a few years, and become stunted, ought to be transplanted now into fresh soil. Ipomœa Learii always flowers best when young in fresh soils.

Greenhouse.—As large portions of air are admitted, more attention to watering is necessary; many greenhouse plants would be much benefited if they could now be turned out into cold pits where frost could be kept from them; our long nights are not favourable to very early spring growth; indeed, nothing can be more injurious to many woody plants than to allow or encourage them to grow early; soft-wooded plants that are annually cut down or close-pruned do not suffer so much from growing out of season.

Forcing-Pits.—There is a good deal of room for speculating on the causes which render plants liable to the attacks of insects. In the forcing-pits we see hardy plants infested on which an insect is never seen in the open air. Moist heat being essential for these pits, less watering is needed; over-watering is a great cause of failure in hardy plants, and a dry atmosphere and sudden changes are nearly as bad. Primulas, Auriculas, Anemones, Pæonies, and almost all plants that flower in April, May, and June out of doors, will force and flower two months earlier if not put into too much heat at first. The whole race of papilionaceous plants will force with less risk than other tribes. It is a good rule to submit all spare ornamental plants to winter or spring forcing.—*H. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

In gardens where the ground was thrown up rough in the autumn, it will by this time be pretty well mellowed; and therefore, as the weather is dry, it would not be amiss to dig the beds over again, so as to bring some more of the soil under the direct action of the atmosphere. Where the ground is poor, enrich it by adding some fresh compost, such as leaf soil, peat, and loam, mixed together, but avoid fresh stimulating manures, or you will have strong rampant plants at the expense of a fine show of flowers.

Shrubberies.—If other work has been got pretty forward for the spring, a few days or weeks might be advantageously spent in regulating the shrubs, such as tyeing misshapen plants into good forms, pegging down branches to get the naked ground covered, and planting a few evergreen trailing plants where such are necessary. Examine your landscape scenery, and see whether, by taking down a tree here and there, or lopping a few branches, you cannot let in a distant object or two that may be worth seeing.

Pits and Frames.—Scarlet and other Pelargoniums planted out in pits for the winter may be potted, and placed in a little heat. The first opportunity, make up a gentle dung-bed for a propagating frame, so as to get to work in earnest, and without any further delay.—*W. P. A.*

III.—FLORISTS' FLOWERS.

The weather is extremely trying to Pansies, Auriculas, Polyanthuses, &c. &c., as this season they will not be so well able to withstand severe cold, not having been inured to it by previous frosts. Florists' flowers grown on beds, such as Pinks, Pansies, &c. &c., may be most advantageously sheltered, by the insertion of small branches of Spruce Fir, about nine or ten inches in length, which not only allow a free circulation of air, so essentially necessary to the well-being of those plants, but at the same time protect them from cutting frosty winds, which all florists know (to their cost) are so highly detrimental.

Tulips.—Attend to the directions previously given; whilst this weather continues, they are going on as well as they can do.

Polyanthuses.—Last week we observed that these plants did best on beds. We have also bloomed them exceedingly fine, by growing them in quart pots, which were placed within others of double size, the space between the two pots being filled with damp Moss, thus keeping the roots secure from those occasional droughts, so encouraging to the red spider, which may truly be said to be the greatest pest these plants have to contend with.

Carnations.—As the time is rapidly drawing on for potting out, look well to your compost heaps; turn them often, and particularly in frosts. Examine your turfy loam, break all the lumps with the back of the spade, and (though not made in vain), destroy without mercy every wireworm you see. It is bad economy to be negligent in paying attention to your soil, as a single insect of this description will often destroy Carnations to a serious amount if overlooked. Should a frost ensue, gather cow-manure from the pastures, pile it in heaps, to decompose; and, in fact, all vegetable refuse ought to be collected whenever opportunity offers.

Dahlias are now being forced, to obtain early cuttings where a large stock is wanted.—*J. F. B.*

IV.—PINERIES, VINERIES, &c.

Pinery.—The temperature of the tanning-pit should from this time be raised one or two degrees a-week till it is 70° by night and 75° by day, increasing the humidity of the atmosphere proportionately. Be particular to have the bottom heat between 80° and 85°. Plants that are now showing fruit, and that are to remain in pots, will be benefited by having some pieces of fibry turf placed in contact with their roots on the surface within the pots, and well up round the collar of the plants, first removing any of the bottom leaves that may be fading, and a little of the old soil. In repotting any of the succession plants that have lost their roots from too much moisture, or other cause, use the soil in a rough fibry state, and as free from sourness as possible. The linings of the pits heated by means of fermenting material will require strict attention now. Keep them dry, and be prepared always with plenty of covering for the roof of your pits, to obviate the injury from sudden decrease of temperature.

Vinery.—During the time the Vines are in bloom, avoid syringing, except on the stem, which should be kept moist. Tye in the shoots as they advance, allowing room for them to swell and stop the laterals. Endeavour to keep the covering upon the border quite dry, as nothing can be more injurious than to have the roots chilled by drenching cold rains. It is now time to shut up the second house; see that the lights are in a clean state, and the house, generally, in perfect order. The Vines in the late house should be pruned, if not already done; any fruit that yet remains should be hung up in a dry cool room.

Peach-house.—During the mild weather we have hitherto had the trees in the succession-house will have been advancing without fire-heat; and it is now time to make slight fires; when the temperature falls below 45°, syringe frequently. Continue to thin the shoots on the trees in the first house; and now when the fruit is set, use the syringe freely.

Fig-house.—Keep a moist, genial atmosphere, and syringe with soap-suds twice a week, to destroy any insects that may be about the buds.

Melons.—As there are many amateurs and gardeners who have

not the advantage of a pit for growing their Melons, the following way of forming a bed may be new to some, and will be found a much better one than making it wholly of dung, as it will not sink so much, nor take so strong a lining to keep up the heat. Mark off the size of the bed on the ground one foot longer and wider than the frame; then build up to this size, with faggots of stout brushwood, to the height of two feet; then lay a row of faggots, 18 inches in diameter, along the back, *front*, and ends, for the frame to rest upon, placing them close and firm, leaving the interior space to be filled up with fermented dung and leaves as a foundation for the soil. The latter should be two feet in depth at least.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Rotation of Cropping.—It is now necessary to determine what the different quarters of the garden shall be filled with during the season. Though one vegetable may be grown on the same ground for years, yet such a method induces a greater expense for manure and labour than when a regular system of rotation is adopted, as the culture of one vegetable often prepares the soil for the growth of another. The chief rule to be observed with all annual vegetables, is never to have two crops of the same class directly following each other. Though excellent plans of rotation may be laid down, yet the period that will *elapse* before the ground is again occupied by a similar crop will depend upon the wants of the establishment and the quantity of ground at the disposal of the gardener. Those who require to have several crops on the ground at the same time, will find that Celery gives a good preparation for Carrots, Turnips, Parsneps, Onions, and early Cauliflowers, or for Peas, with Potatoes and Winter Greens, or Broccoli between the rows. Autumn-sown Onions may be succeeded by Spinach, Lettuce, &c., and early Cauliflower by autumn Onions. Spring-sown Onions will be advantageously succeeded by Cabbages in beds, with Scarlet Runners between; and if the Cabbages stand all summer and next winter, the ground will come in, in the spring, along with Broccoli-ground, for Celery, Potatoes, and Peas, the early Potatoes being planted in the trenches, and the Peas sown on the ridges.

Peas and Beans.—Sow a quantity in a little heat in pots, or on turf, to turn out in the middle of March.

Radishes, Carrots, &c., may be sown on a warm border, and covered up with litter. The weather is now so very changeable, that instead of planting or sowing much, it will be more advisable to get all the ground at liberty in good order by frequent digging, ridging, &c.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Under this head proceed with the works as directed in previous Numbers.

Coppice.—Refer to the directions of last month, and perform all necessary works in due time.

Young Plantations.—Attend to training, relieving, and thinning, as directed last month, from the second or third year after planting till the trees attain the height of 15 or 20 feet. Many people imagine that after the trees are planted they require no more attention for several years, but this is a great error.

Hedge-rows.—As many persons will now be putting their fences in order, and planting trees in hedges, some would, perhaps, like to know what kinds should be preferred; but this depends entirely upon the soil and locality—those kinds that would succeed in one place might not do so in another. In sheltered situations and in dry soils, the Walnut, the Locust-tree, the Gean or Wild Cherry, the Hagberry or Bird Cherry, and Mountain Ash will do well; but the Oak and Spanish Chesnut require a good soil. The Scotch Fir and the Larch thrive on high situations; the roots of these run near the surface, and are injurious to arable lands. Compact upright-growing Elms answer for hedge-rows, but not the forked Wych or Scotch Elm, yet even that might answer, if properly trained. Ash should only be planted in pasture or meadow land.

Nursery Work.—Having previously alluded to the injury done to young trees in nurseries and plantations by hares and rabbits, the following is a simple and cheap method I have used for several years to save young Apple and Locust trees from them, but this process will not answer in extensive plantations:—I make a mixture of cloacine (fresh night-soil), rather in a liquid state, but if that cannot conveniently be got, fresh thin cow-dung, soot, sifted coal or wood-ashes, diluted with strong soap-suds to the consistence of yeast, may be smeared over the stems and branches, as high as the hares or rabbits can reach, with a brush made of Ling (Heath) thrums, or Wheat-straw with the ears on. This should be applied early in November, or before severe weather sets in; it should be laid on pretty thick, once or twice, on a dry day. It will secure them for one winter. No danger arises from it, and it will wear off in spring. Many choice shrubs and flowers might be preserved by sprinkling them thickly over with this mixture early in winter.—*W. B.*

VII.—COTTAGERS' GARDENS.

As the weather within the last few days has been very changeable, the cottager should pay particular attention to protecting everything that is likely to be injured by frost. When the nights are sharp and cold, all the plants should be drawn back from the window, or set down on the floor of the room. Pelargoniums, owing to the late mild weather, will now be handsome bushy plants, if they have been well treated, and must be carefully watched; if they incline to grow up weak and slender, the points of the shoots may be nipped off; they should be watered sparingly and allowed to have plenty of air every fine day. Daphne odora rubra makes an excellent window plant, and may be made to bloom freely at this season if it is treated as follows. A plant of it, I am informed, was potted last spring in coarse rich loam and charcoal; about the beginning of June it was turned out, in the pot, into a shady border until it had finished its growth. In the middle of August it was put, still in the pot, into a border due south where the wood got well ripened; it was taken up in November and placed in a window. It is now looking very healthy and has 11 bunches of flowers on it. This plant is grafted, like a standard Rose, about 14 inches high.

Vegetables.—If not done last week, a sowing of Radishes may be made on a warm border if the weather is favourable; but the beds must be carefully covered in severe weather, as directed in last week's Calendar. Vacant grounds, if any, may be dug, and everything that will forward the spring work should now be done before that busy time arrives.

Fruit.—If any fruit-trees still remain not pruned, it is not yet too late to perform that operation, taking care to keep the branches thin and regular.

Flowers.—This changeable weather is very unfavourable to flowers, and they will require much attention. If severe frost sets in, China Roses, &c. trained on the cottage should have some protection, for being in a forward state, they will be injured by it. Spring-flowers, as Anemones, Tulips, &c., if any, must also be looked after, and protected with fern or straw.—*Mall.*

State of the Weather near London for the week ending Feb. 1, 1844, as observed at the Horticultural Garden, Chiswick.

The highest temperature during the above period occurred on the 10th, 1831.—thermometer 65°; and the lowest on the 8th, 1839.—thermometer 19°.

Notices to Correspondents.

OUR CORRESPONDENTS will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

COMMUNICATIONS from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them:—*A Practical Man, P. Mackenzie, J. Wighton, O., M Power, H. Groom, A Friend to Floriculture, Nemo, J. M'I., M. T. B., J. W., J. L. Snow, G. Thompson, I. W. K., Vitis, W. Billington,* and *Martin Doyle.*

AMPHICOME ARGUTA, &c.—*A. Scot.*—This may be potted in loam and peat mixed with a little sand; Astelma Stschelina will succeed in turfy peat, mixed with sand; both of these are greenhouse plants, and will flourish in a temperature from 40° to 50° in winter; but Cypripedium venustum and Gesnera faucialis require a temperature of about 65° at that season, and therefore cannot be grown among greenhouse plants.‡

ASPARAGUS.—*A Reader.*—You may apply during the ensuing spring to Asparagus-beds in a bad condition, both salt and the mud you mention from a pond formed by farm-yard drains and house-sewers. ‡

AURICULAS.—*A Novice.*—Top-dress with leaf-mould, cow-dung, and sand, equal parts. Try one or two with superphosphate of lime instead.

AZALEAS.—*An Amateur.*—The following are 12 distinct handsome hardy hybrid Azaleas, viz.:—eximia, luteo rubicunda, coccinea nobilis, Gloria Mundi, incarnata maxima, regalis, amabilis, Govenia, thyrsiflora, Aurora, dulcedo, blandina.¶

BOOKS.—*An Old Subscriber.*—"Mackintosh's Practical Gardener."——*W. J.*—"Glendenning on the Pine," and the last No. of the "Gardeners' Magazine."——*S. N.*—The "Theory of Horticulture."——*A Novice.*—"Turner's Chemistry." You should read Sprengel's papers, as translated in our columns. Lime drives off ammonia.——*W. E. C.*—You should apply to Mr. Sowerby. We do not know.

CELERY.—*Moderator.*—In order to get this early, without much risk of the plants running to seed, it should be sown in shallow pans about the beginning of March, and placed in heat until it forms its first leaves, when it should be pricked out into a cold frame, and remain there until May, when it may be finally transplanted into the open ground.‡

COPPICE.—*A. C. P.*—You may plant any time up to the end of February. The best time is in the autumn. The better the soil is prepared, the faster the trees will grow; but single trenching, if the drainage is good, is enough. Without perfect drainage, it is useless to plant anything better than Alders and Willows. No manure is required; but if you could pare and burn the whole field in the course of next summer, you would gain much more than you would lose by waiting one season. Oak, Ash, Hazel, and Bird-cherries, are what you must chiefly rely upon.

CHRYSANTHEMUMS.—*An Amateur.*—The following are good kinds, viz.:—formosum, Duc de Canegliano, Therese, Eclipse, Beauty, Grand Napoleon, Princess Maria, Minerva, Goliath, Vesta, Queen, lucidum.¶

FOSSIL FERNS.—*C. R. Bree.*—The belief in the existence of gigantic fossil Ferns in the coal measures is founded upon the existence there of Sigillariæ, an extinct form of vegetation of considerable size, which Adolphe Brongniart has referred to Ferns. But this has long ago been shown, in the "Fossil Flora," to be a conclusion entirely unsupported by evidence. It is true that the ingenious French Botanist has attempted to prove his case by a long and elaborate argument; but if such reasoning as he employs in doing so is to be admitted, then anything may be proved. In fact, we believe that Adolphe Brongniart has himself changed his opinion, and admitted his error. It is true that a few fragments of real Tree Ferns are found in the coal measures, and have been distinguished by Lindley under the name of Caulopteris, but there is nothing gigantic about them; they are, in fact, exceedingly like Tree Ferns now inhabiting the tropics.

FRUIT-TREES.—*A Subscriber.*—The ground which you have allotted for a small orchard, 30 yards square, will contain, at 6 yards apart, 10 Apple trees, 10 Pear, and 5 Plum-trees. They may consist of the following varieties:—*Apples*—Ribstone Pippin, Blenheim Pippin, Claygate Pearmain, Dutch Mignonne, Golden Reinette, Stormer Pippin, Court-pendu Plat, Alfriston, Wormsley Pippin, and Dumelow's Seedling. *Pears*—Marie Louise, Bacon's Incomparable, Beurré Diel, Knight's Monarch, 2 Glout Morceau, 2 Passe Colmar, 2 Beurré Rance. *Plums*—Royal Hâtive, Orleans, Green Gage, Purple Gage, and Washington. ‖

GREENHOUSE CLIMBERS.—*S. H.*—The following are suitable for covering the back wall of a greenhouse 30 feet long and 10 feet high, viz., Clematis azurea grandiflora, C. Sieboldii, Cobæa scandens, Maurandya Barclayana and Kennedya Marryattæ.‡

HARDY PLANTS.—*L. M. C.*—The following plants are suitable for an open border, and may be easily obtained, viz.:—Pæonia Moutan, white, 3 feet high, flowers in March and April; Thermopsis fabacea, yellow, 2 ft., flowers in May and June. The following 12 flower in October and November:—*Red:* Betonica serotina, 1 ft.; Eupatorium trifoliatum, 2 ft.; Aster Novæ Angliæ ruber, 3 ft. *White:* Gnaphalium margaritaceum, 1 ft.; Aster diffusus, 2 ft.; Aster lævis, 3 ft. *Blue:* Statice Gmelini, 1 ft.; Stenactis speciosa, 2 ft.; Aster Novæ Angliæ, 3 ft. *Yellow:* Rudbeckia hirta, 1 ft.; Gaillardia aristata, 2 ft.; Pascalia glauca, 3 ft. August and September—*Yellow:*—Gnaphalium arenarium, 1 ft. The kinds of Perennial Aster that flower up to Christmas are handsome; but they are generally injured by frost, and become unsightly before that time. Iberis semperflorens is quite hardy and handsome; it does not flower all the year round. Saxifraga ligulata flowers in May; its blossoms are nearly white, with a slight shade of pink; it grows about a foot high, but is not a hardy perennial. Helleborus orientalis keeps in bloom from December to February; Anemone hortensis flowers in May; Arabis rosea will bloom early in January; Andromeda floribunda puts forth its pretty white blossoms in March and April; Lathyrus magellanicus has blue flowers; being rather tender it succeeds best when treated as an annual. There are some Narcissi that flower in September: N. viridiflorus. ¶

HEATHS.—*An Amateur.*—The following are 12 distinct hardy Cape Heaths, for flowering during the summer months, and they may be easily procured, viz.:—Bowieana, white; grandiflora, yellow; ventricosa, pink; echiiflora, purple; Beaumontiana, blush; mamula, pink; cerinthoides, scarlet; ampullacea, aristata, dark, crimson, and pink; aggregata, purple; viridiflora, green; and physodes, white.¶

HIBISCUS.—*J. W.*—Your seedling plants of Hibiscus, that have lost their leaves from damp and the effects of green-fly combined, may be cut down and placed in heat; they will start away again from the root. They are not difficult to raise from seed; but many of them are stove plants, and require a higher temperature than that of a greenhouse. Your Carnation layers may be separated from the parent plants in March ‡

LEUCATHEA FORMOSA.—*F. K.*—This plant was introduced in 1821. It is a native of the Himalayan Mountains, and is handsome, but its flowers are not very conspicuous. It is perfectly hardy, and forms good cover for game, as pheasants are fond of its berries. ‡

MANURES.—*A Subscriber* may use guano at the rate of 1lb. to 4 gallons of water for watering Pines and other plants. Coarse charcoal mixed with the soil has a beneficial effect on Pines and greenhouse plants.‡

MELONS, &c.—*L. B. V.*—You cannot grow Vines and Melons with advantage in the same house, when the Melons are to be trained on a trellis under the lower lights and the Vines over the upper ones; but Musas and other tropical fruits that will bear a uniform temperature, and that you wish to grow, will succeed very well on the back part of the house, where there is a stage 3 feet wide with a tank under it. When the Melons have done bearing, their place may be filled by Cucumbers during winter. In the same house you may also force Kidney Beans.‡

NAMES OF PLANTS.—*Calos.*—Your Syrian plant is some kind of Cyclamen which we do not recognise. Keep it in a greenhouse, while in flower, at this time of the year, and place it out of doors in a warm sunny place during summer. Bring it back into the greenhouse when the rain and cold of autumn commence. Few directions have yet been given for pruning, except incidentally. Some very good ones are to be found in the "Cottage Gardens" of 1841, especially Nos. 42 and following.——*A Botanist.*—Hypnum rutabulum; pray do not ask us to name Cryptogamic plants having no relation to gardening.——*Tregye.*—The yellow variety of Maxillaria variabilis.—*E. M.*—Æschynanthus grandiflorus.——*D. W.*—The Cashew Nut.——*Lepus.*—Your seeds certainly belong to Smyrnium olusatrum; but whether it is palatable to rabbits we do not know. Most likely. It is an old-fashioned potherb.

THE OLIVE.—*J. N. V.*—The seed of this plant will not keep, and therefore cannot be sent to great distances. It varies in quality, but not so much as Apples. The best of the cultivated kinds are those of the north of Italy; the worst the Spanish. The wild Olive is very inferior, and of little value. The only certain way of sending Olive-trees to the most distant colonies is in Ward's cases, in which they will travel for six or seven months without care and without injury. They may be had of Messrs. Loddiges. The finest trees are said to be those which grow in moist rich soils, but the best oil is reputed to come from the warmer chalky districts. In the Olive countries the tree is propagated by truncheons chopped off the stools, with a few roots adhering. It may also be increased readily by layers. Such plants are said to fruit in two or three years. We do not know how long seedlings are before they bear, but probably several years.

ORANGE-TREES.—*A. Z.*—Your Orange-trees may be repotted in March. A rough soil, consisting of two thirds sandy loam and one of fibrous peat, will suit them best. The pots should be well drained, and charcoal, or if that cannot be procured, brick-rubbish may be freely mixed with the soil. Orange-trees should be placed out of doors during summer and autumn, when they require no further care than to attend to them with water. In winter, when in doors, they may be managed like other greenhouse plants. They like the very strongest manure.‡

ORANGE-TUBS.—*A Subscriber.*—To paint the inside of these with pitch (not coal-tar) is not injurious to the plants, and it renders the tubs more durable than they would be without it.‡

PSEUD-ACACIA.—*D. C. L.*—This will bear cutting down very well, and throws out a quantity of brushwood where it is cut; but it will not form a thick strong underwood capable of keeping trespassers out of plantations.‡

TRANSPARENT CALICO.—*Subscriber.*—Just tack your calico to your frame before you apply the composition; when it is dry it will become slack. Then unfasten it, strain it tight, and secure it. Most likely it will want a second coat of composition. We have no idea that the substance you mention is so good as Whitney's, which is the most transparent that we have seen.

VINES.—*A. B. C.*—When the fruit is cut, the Vines in your late Vinery should be pruned immediately, and successively as the crop on each Vine is cleared off. Having Pine-apples and Vines in the same house, you cannot do justice to both, and obtain a late crop of Grapes, without the means of turning out the Vines, which you say you have not. If the sashes were made to slide there would be no difficulty; for the lower ones could be drawn up so far as to admit of the Vines being taken outside, and the space at bottom could then be closed by Whitney's prepared calico.‖

MISCELLANEOUS.—*B. F. K.*—Onopordum acanthium is mentioned by Sir W. Hooker as the Scotch Thistle; but we have always supposed it to be Cnicus lanceolatus.——*A. V.*—Twopence each paper.——*Alpha* is answered by Mr. Fleming's paper in last week's *Chronicle.* The Cabul Melons are generally excellent, but no doubt some of the varieties cultivated in Afghanistan are inferior.——*T. W.*—Your questions cannot possibly be answered in a newspaper. We advise you to consult Mr. Glendinning, of Turnham Green, whose opinion you may take with confidence.——*Inquirer.*—There are many substances which cannot be converted into a gaseous form by any known force, such as several of the metals. Nevertheless, it is not improbable that all matter has a gaseous origin; and Professor Lowe, in his late work on the simple bodies of Chemistry, supposes that the only elements of matter may be oxygen and hydrogen.——*A. Y. C.*—Much obliged, but have bought as many Numbers as we want at present.——*J. D.*—Your seedling Azalea has fine flowers, but far too much like other pink ones.——*A Subscriber.*—The kitchen-garden at Kew, or that part containing the Pineries and Forcing-houses, is never open to the public. ‡——*H. C.*—Bricks are conductors of heat, but very bad ones, if compared with metals; the difference between them and gold is as about 10 and 1000.——*B. B.*—We do not know how the French stain their boards so as to make them look dark; but a strong infusion of galls washed over wood that had been previously moistened with sulphate of iron would produce a very dark colour.——*Y. E.*—Those who tell you that it is pedantic to call uncommon plants by their botanical names are themselves the pedants. A large part of our wild plants, and most exotics, have no recognised English names, but are sometimes called one way and sometimes another. Their botanical names are the only ones that are stable. It would be pedantic, no doubt, to call the Hawthorn, Crataegus oxyacantha, and to give Latin names to very common plants in *common conversation*; but with this exception, there is no more pedantry in the matter than in saying Birmingham instead of Brummagem. Those who cry out at Botanical names are they who are ignorant of them, and would have every one else like themselves. You know the *fox*, when his tail was cut off, tried to persuade his brother foxes that tails were out of fashion, and only stumps the mode.——*M. D.*—An article on the Mistletoe will appear in our columns soon. ‡——*A Lady.*—The Beech wood is an excellent Melon; seeds of it may be procured from any respectable seedsman. ‡——*Micklewell.*—Notice concerning subscriptions for Mrs. London will be given in due time. The Lily with purple-backed petals is japonicum.——*A Constant Reader.*—Sorry we cannot answer your question, but you must be so obliging as say to *what* mode of heating you refer? Give us page, &c., and we shall know how to reply. Leaves should be moist, not wet, when they are thrown in a heap to ferment. If mixed with hot dung they moderate its action.——*A Subscriber.*—We cannot tell. You should ask Mr. Groom himself.

*** As usual many communications have been received too late for answering this week.

LARCH PLANTS. — One and two years' transplanted; of good size and quality. On Sale by DICKSON and TURNBULL, Nurserymen, Brechin, N. B.—Will be sold cheap, and freight paid to London.—Brechin, Feb. 1, 1844.

LARCHES.—The Subscribers have still a Large Quantity of fine Transplanted LARCHES of sizes which they are selling at very low prices.—WM. URQUHART and SONS, Dundee.

MIXED GRASS SEEDS, FOR PERMANENT PASTURE AND LAWNS.

ROGER SMITHE, of Eastling, Faversham, Kent, has for sale the above Seed at 8s. per bushel, three bushels per acre, containing all the best sorts, with a good proportion of the Clovers and Trefoils properly mixed for the generality of land. Persons are requested to name the soil as the mixture will be regulated by that. Also all other Seeds proportionably low. These will be sent to any part of the Kingdom.

The Agricultural Gazette.

SATURDAY, FEBRUARY 3, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Feb. 7 . { Agricultural Society of England. Highland and Agric. Society.
Thursday, Feb. 8 . Agric. Imp. Soc. of Ireland.
Wednesday, Feb. 14 . Agricultural Society of England.
Thursday, Feb. 15 . Agric. Imp. Society of Ireland.

"THE PROFITS OF FARMING, whether the land be pasture or arable, and the tenant be a feeder of stock or a tiller of the ground, may be increased in two ways.

"The stock-farmer knows very well that the return he obtains from his cattle depends not only on the kind of food given to them and the manner in which it is supplied, but also on the feeding properties of the breed to which they belong; and he increases his chance of profit as much when, on purchasing from the breeder, he selects with judgment, as when he adopts an improved mode of feeding.

"The intelligent farmer of arable land, again, expects a greater crop the more he has been able to improve the texture of the soil, and the better the nature and state of the manure which it contains. He expects it, because he knows that it depends on the nature of the food given to the plants, and the manner in which they are provided with a constant supply of it. The crop does not, however, depend wholly on this; for as two beasts fed in exactly the same manner may not be equally profitable, owing to a difference between them regarding the quantity and the quality of the meat they afford, so two different kinds of Wheat, though sown on land precisely similar, may give unequal returns, owing to a difference between them regarding the quantity and quality of the flour they afford. Hence the importance, too often overlooked by farmers, not only of preparing the land for the crop in a good and sufficient manner, but also of selecting that kind of seed which experience has pointed out as being most valuable and productive."

We quote the above from an article by Mr. Morton in the first part of the first volume of the English Agricultural Society's Journal. The parallel between the circumstances affecting the stock farmer and those affecting the corn farmer is true, even when carried into detail. The quality of that which is reared by the one, upon which (if we put out of sight the kind and quantity of food supplied by him) his profits depend, is made up of the same elements as that of the articles reared by the other. An aptitude to fatten—*i. e.*, a capability of producing a large quantity of beef or mutton from the consumption of a given weight and kind of food—and the quality of the beef or mutton so produced, *i. e.*, the price per pound they will command in the market, are the two circumstances which determine, in the eye of the stock farmer, the value, to feed, of any breed of cattle or sheep. And, taking the instance of the Wheat-crop, the corn-farmer, on the other hand, in selecting any variety for cultivation, must not only take into account its productiveness, but also its quality in the eye of the baker.

Little attention has hitherto been applied to that branch of cultivation which refers to the selection of seeds. The branch of farming which constitutes the business of the stock-farmer has received much more attention and more patronage from the noblemen and landowners of the country than the mere art of cultivation; and the consequence is, that the breeding and feeding of stock is generally well understood and skilfully practised, while large districts are still badly farmed. We are therefore glad to see the announcement of a work, by one of the body we allude to, on this comparatively neglected subject.*

This work is addressed to farmers and bakers. For the benefit of the former, it was necessary to ascertain the extent of the difference existing between several varieties of Wheat, and the degree in which this difference is affected by the circumstances of cultivation, &c.; for the latter it was important to know how far the criterions by which they at present judge of the value of samples submitted to them, are trustworthy. These two subjects are both considered, and the questions arising out of each are answered in detail, and at the close of "the remarks," the importance is insisted on of our great Agricultural Societies taking up this and other questions in a manner which alone can ensure their perfect solution, by establishing experimental farms.

The general character of this work is well indicated by the following extracts:—

"The first object I had in view on entering into the present inquiry, was to ascertain whether, under the same circumstances, in reference to soil and climate, different varieties of Wheat were, chemically, differently constituted. This I have ascertained to be the fact, by having had nine varieties which grew together on the same spot chemically examined, viz., the first five in the tables, and the four mentioned in page 9. With respect to Nos. 7 and 8, they are the same variety, the one sown after Potatoes being the richest in gluten and sugar, that sown after pasture-grass the poorest. This result proves what might have been expected from the statement of Liebig, respecting the advantage of stirring and exposing the soil. Long before Liebig had published his works, I had observed the advantages of the stirring which the land receives for the Potato and Turnip crops; and such of my tenants as have followed my advice to make either of these the first crop taken from new land, have found it better than taking Oats, according to the old custom. Liebig has informed us how stirring the earth renders it more productive.

"The next object I had in view was to ascertain whether external appearance and the weight of a given bulk were sufficient to indicate the actual value of Wheat to the baker and starchmaker."

These objects were attained, the first, as stated in the extract, by a chemical examination of certain varieties which had been grown under similar circumstances, and the second by submitting these very samples to the inspection of Corn-factors and obtaining from them opinions of their value. The results of this inquiry are given in the following Table:—

CHEMICAL ANALYSIS OF EIGHT VARIETIES OF WHEAT.

Wheats.	Gluten*	Starch and Gum.	Sugar.	Bran.	Water.	
1.	17·70	66·80	3·50	2·3	10·00	Pale Red Cape Wheat, 63 lbs.
2.	10·19	69·94	2·77	2·57	14·6	Duck's Bill Wheat, 63 lbs.
3.	20·8	56·8	5·0	2·8	14·6	Black-Jointed Tremaine Wheat, 62 lbs.
4.	16·90	66.20	4·50	1·9	10·50	Grano Duro, of which Macaroni is made, 63½ lbs.
5.	20·60	53·04	3·70	2·0	10·60	Grano Tenero St. Brigida, 63 lbs.
6.	15·60	70·25	3·25	1·6	10·30	From Port Adelaide, South Australia, 65 lbs.
7.	17·8	60·0	4·6	3·9	13·6	Red Wheat, sown after Potatoes, 65 lbs.
8.	16·2	60·9	4·2	4·0	14.7	The same after Lea, 65 lbs.

* This Gluten includes all the nitrogenous products of the Wheat.

"The first five were grown on the same spot, all circumstances of soil and climate being the same. Also other four sorts which were examined solely with the view to compare the weight per bushel with the quantity of gluten. The first weighed 64 lbs., and contained, 15·86; the second 61 lbs., and contained 14·64, showing a difference in 3 lbs. per bushel of 1·22 per cent. The third weighed 61 lbs., and contained 9·8; and the fourth, 65 lbs., and contained 10·3; showing a difference in 4 lbs. per bushel of 0·5. It is seen by the tables, that, in equal weight, there is difference of proportion among all the ingredients, so that weight indicates nothing in reference to proportions."

The Wheats referred to in the following Table are the same as those mentioned in the one above, and while the extraordinary difference between the figures affixed to some of these varieties shows how little "judgment from external characters may be relied on, in reference to the opinions of different individuals," a consideration of these figures with reference to the composition (see 1st Table) of the Wheats, of which they are the prices, demonstrates still more clearly, of how little value the various appearances are, by which Wheat has hitherto been judged of. It must be recollected that the proportion of gluten in Wheat is a main element in its value; the more of this substance flour contains, the more nutritious is the bread, and the more perfect is the operation of baking.

Wheats.	Prices by three Corn Factors.			Prices by three Bakers.			
	s.	s.	s.	s. d.	s. d.	s. d.	
1.	50	50	52 0	52 6	48 0	52 0	Pale Red Cape Wheat, 63 lbs.
2.	53	52	53 6	53 6	52 6	53 0	Duck's Bill Wheat, 63 lbs.
3.	46	46	48 0	51 0	50 0	46 0	Black-jointed Tremaine Wheat, 62 lbs.
4.	42	42	40 0	50 0	*	*	Grano Duro, of which Macaroni is made, 63½ lbs.
5.	40	45	42 0	48 0	*	45 0	Grano Tenero St. Brigida, 63 lbs.
6.	55	56	57 0	55 0	56 0	51 6	From Port Adelaide, South Australia, 66 lbs.
7.	51	50	52 0	49 6	52 0	50 0	Red Wheat, sown after Potatoes, 65 lbs.
8.	50	50	50 0	49 6	48 0	50 0	The same after Lea, 65 lbs.

* These Wheats being new to them they could not fix a value.

"Had the Wheats been mixed samples, a variation in the values might not have excited much surprise; but in the present case the samples were each of one sort, and unmixed; so that there could be no distraction to the eye, every one of the grains in each sample being exactly alike."

Here we see samples 3 and 5, of the same weight per bushel as No. 2, and containing more than double its quantity of gluten, yet valued at 6*s.* and 9*s.* less per quarter. If the quantity of gluten contained in Wheat be the true criterion of its value as food, then the above tables clearly show that the guides, now made use of by millers and bakers in valuing Wheat are not trustworthy.

Most of the Wheats mentioned by Sir G. Mackenzie appear from their names to be foreign, but the great differences which he shows to exist among them seem, from Colonel le Couteur's Paper on this subject in vol. i. of the English Agricultural Society's Journal, to be equally apparent in varieties now commonly cultivated. This is seen in the account given of the quantity of bread made from equal weights of the flour of several kinds of Wheat. To whichever component part of the flour the absorption of water in the preliminary processes of baking is owing, the fact that different quantities are absorbed by different varieties shows that the proportion these component parts bear to one another in those varieties is variable; thus:—

9 lbs. of flour of Bellevue Talavera Wheat made 11 lbs. of bread.
9 lbs. of flour of Whitington White Wheat made 11½ lbs. of bread.
9 lbs. of flour of Jersey Dantzic Wheat made 12½ lbs. of bread.
9 lbs. of flour of White Downy Wheat made 12¼ lbs. of bread.

It appears, then, from the extracts we have made from Sir G. Mackenzie's valuable Pamphlet, that great differences do exist amongst varieties of Wheat, as regards the quality of their flour, and that no external indication is known by which these differences may be estimated.

ON THE AGRICULTURAL VALUE OF LAND.

(Continued from page 58.)

II. The value of land depends in great measure on the cultivation it has received.

The cultivation of land may be divided into three distinct branches, in each of which it influences the fertility of the soil.

1st—In the application of manures.

2d—In the pulverisation given to the soil by Agricultural implements.

3d—In the nature of the crops cultivated, and the manner in which these are made to succeed one another.

1st—The texture of a soil, though mainly dependant on its mineral composition, and therefore to be permanently improved only by an alteration in its mineral composition, depends, partially, and may, in some degree, be altered and improved by the cultivation it receives. The addition of some kinds of manure to a tenacious soil tends to make it looser, and will improve its texture, but the effect is not permanent, for the manure added becomes decomposed and its effects disappear if a fresh quantity be not applied. Manure, however, does not in general act as a means of improving the texture of the soil, but as a source whence the plants growing on it derive their nourishment.

From the researches of physiologists it appears that plants are incapable of making use of anything insoluble. The roots, through which all nourishment derived from the soil must pass, are terminated by a membranous substance termed a spongiole, which is so fine that nothing in mere mechanical suspension in water, can pass through it. Only those substances, therefore, which are at present soluble, or become so by exposure to the weather, are useful as manures; substances incapable of solution by ordinary natural agents may frequently, indeed, be made use of with advantage to alter and improve the texture of the soil, but they are useless as sources of nourishment to vegetation. The fact that the value of manure depends so much on its solubility seems to be generally neglected amongst farmers. Dung-heaps are often seen placed on some piece of waste land near the farm buildings, and are there suffered to dwindle away during a course of years, that they may be the more thoroughly rotted. One half, at least, of the weight of the manure is thus lost, and this is by far the most valuable half. The rain has carried away to some neighbouring brook all that was soluble in it, and the gases evolved during its decomposition have been given off to the air. The remainder is carried to the pasture lands, but in its then condition it can do them but little good. In some cases, however, the dung-heaps are managed a little better; clay or mould, or the scrapings off the roads being mingled with the manure, tend to retain the liquid and gaseous portions which would otherwise be lost. It is made in yards, where it lies during the summer and autumn, and after being cast up into heaps during winter is carried out to the Turnip-land, where it receives one or more turnings before being spread over the land. Here also, however, the rain is suffered to wash away to the horse-pool or elsewhere the soluble, and therefore the most valuable, part of the dung. Of farm-yard manure generally the two most valuable parts, the washings of the manure, and the urine of the cattle and horses, are lost: these might be collected in tanks in the yards, and being carted out over the arable or pasture land, or being spread over the dung when it was dry, would be found of the greatest value to the farmer.

The following Table gives the result of an experiment re-

* Brief Remarks on some Subjects connected with the Choice of Wheat for Seed, interesting to Farmers, Agriculturists, and Bakers. By Sir G. S. Mackenzie, Bart., F.R.S., L. and E., &c. Simpkin and Marshall, London.

garding the use of dung-water as a manure; it was applied in much too small a quantity.

Barley sown	Barley	Straw	In-crease	In-crease.	Val of man.	Cost	Pro-fit.	Loss	Soil.
Dung-water 300 galls. per acre.	s. c. q.	ct qr lb.	s. c. q.	ct qr lb.	s. d.	s.	s. d.	s. d.	
	43 0 6	27 3 12	2 2 0	2 3 9	11 10	2	9 10		
Saltpetre 1 cwt.	45 2 0	32 3 19	4 4 0	7 3 12	25 10	28	——	2	Stone Brash.
Nitrat. soda 1 cwt.	51 2 1	35 2 24	10 4 1	10 2 21	52 10	20	32 10		
Crop without manure	40 6 0	25 0 0							

A proper attention to the preparation of manure, and to the application of it in kind and quantity suited to the nature of the plant cultivated, would be influential in increasing the fertility of the soil.

2d—The stirrings given to land during its cultivation influence its fertility in two ways: by assisting the decomposition of the manure in the soil, and by giving a depth of loose land in which the roots of the plant may spread. In both of these, the depths of the stirrings and the fineness to which the mould is reduced by them are of the greatest importance. In the state in which manure is generally applied to land, it is useless, it is only after undergoing a process of fermentation in the soil that it becomes a source of nourishment. The products of that fermentation are soluble, and therefore admit of being taken up by the roots of plants. The presence of air is necessary for fermentation, and therefore land is in a proper condition only when in such a state of looseness that air has free access to every part of it. The proper degree of looseness varies, of course, with the plant cultivated. Thus in the case of the Swedish Turnip, which requires large and constant supplies of nourishment, the land should be as loose as possible, not only that the root may be able to increase in bulk, but also that the manure in the soil may rapidly undergo fermentation, while in the case of the Bean, or of Wheat, the nature of the plant requires a considerable degree of firmness. A degree of looseness in the soil and subsoil doubles the resources of the land. It is not liable to injury under extraordinary circumstances, as in the cases of extreme drought, or of extreme wetness. The roots of the plants, in the one case, stretch far downwards beyond the drying influence of the sun and air, whence they can supply the plants with moisture; while in places where the subsoil has been left firm and unstirred, the plants are withered for want of it. In the other case, if the stirring of the subsoil has been effected after a thorough drainage of the land, the plant is uninjured by the rain which, stagnant on land not thus treated, destroys the vegetation covering it. —*M.S.*

(To be continued.)

IN WHAT CONSISTS THE FERTILISING QUALITIES OF BONES?

While every farmer occupying a sandy or peaty soil will acknowledge the incalculable value of bones as a manure, scarcely two practical agriculturists or chemists will agree as to what portion of the bones it is which furnishes the fertilising principle. Sufficient facts, however, seem now collected by the former class of persons, and sufficient analyses made by the latter, to furnish data to enable us to decide this not unimportant question; for it is only by ascertaining the precise fertilising principle of bones, that we can certainly calculate when certain soils are in need of a dressing of them, and when they are an injudicious application.

As regards the practical results of their application, we may safely lay down the ascertained facts, that they are most useful to peats and sands, and least useful to tenacious soils. It is likewise established that they are, of all crops, most useful to Turnips, and succeed when applied alone, in producing many tons per acre, on land which without manure would not mature a single plant.

It is settled, too, according to the authority of Fourcroy and Vauquelin, that bones consist of

Decomposable animal matter	51· Parts.
Phosphate of lime	37·7
Carbonate of lime	10·
Phosphate of magnesia	1·3
	100

Now the question arises, is it the mineral or gaseous principles to which their value is to be referred, seeing they contain these in nearly equal proportions?

To begin with the mineral. Many writers contend that this is the element to which bones owe their value. The Highland Society of Scotland offered the gold medal for the best essay on the subject of the fertilising qualities of bones as compared with farm-yard manure, and the prize was awarded to Dr. Madden, who gave it as his opinion, that the value of bones was principally due to the phosphates which they contain. His calculations, however, have been proved to be fallacious, and are known to be quite erroneous in principle, though at the time they were thought by some to have settled the question.

Now, admitting that about six cwt. of bones is the average application to an acre of land, something like 2½ cwt. of phosphate of lime will be applied to the soil; on the other hand, calculating twenty tons as an ordinary dressing of fold-yard manure for Turnips, and calculating it to contain, on the very lowest average, three per cent. of phosphate of lime, we shall have no less than twelve cwt. of phosphate of lime supplied by it to the crop. If it were the phosphate of lime to which the whole of the credit were due, how does it happen that bones are peculiarly beneficial to Turnips, which, compared with many other plants, contain but a small comparative per centage of it, and why is it not equally efficacious on clay soils, where there is so constant a drainage of their phosphates by taking away the Wheat? and why is it so useful on peaty ground, which generally abounds in phosphates? To show that we have not over-rated the phosphates in farm-yard manure, under ordinary circumstances, we may just refer to Liebig, who gives horses' dung as containing 5 per cent. of phosphate of lime, cows' dung 10 per cent., and straw varying from 7 to 16 per cent.

As regards the very small quantity of phosphate of magnesia, the above remarks apply in greater degree.

Is it, then, the spinal matter—consisting principally of gelatine, but also containing some fat, oil, and cartilage, to which bones owe their value? Gelatine, according to Gay, Lussac, and Thouard, consists of the following proportions of—

Carbon	47·88 Parts.
Oxygen	27·207
Hydrogen	7·014
Azote	16 998

It would therefore appear that bones contain about 8 per cent. of azote, and to this we submit, nearly the whole of their fertilising qualities owe their existence. Azote is the principal feature in all powerful or concentrated manures—the base, so to speak (if the term may be allowed in this sense) of all the forms of the nitrates, and the compounds of ammonia—two forms of gas by the quantity of which, as by a standard, nearly all manures may be reckoned in value, because crops supplied with a full quantity of azotised manure invariably excel in luxuriance, being thereby enabled to assimilate a greater quantity of their other constituents.

The great value of bones, moreover, above many other azotised manures, consists in its having its peculiar elements in a state of considerable fixity. While the nitrates require only solution in the soil to set free their azote with great rapidity, and while the various forms of ammonia are even still more volatile, the gelatine in bones requires to be fermented, and to undergo a process of decomposition anything but rapid, before the azote will be given off; and when it is so given off, it is in a way so gradual, as to be in strict applicability to the wants of the plants.

It has been asked, with some degree of confidence, if the bones owe their utility to the gelatine, how does it happen that burnt bones are also in some cases decidedly advantageous applications as manure? The experimenters, however, did not say how they were burnt. If they were burnt to whiteness, so as to crumble to powder, doubtless they would be deprived of the whole of their azotised matter; and if these were equally useful with unburnt bones, doubtless practice would decide against our theory. But if the bones were but partially burnt, only to blackness, or burnt in a confined position, the azote would not be dissipated in any great quantity, but only made more volatile, and therefore likely to produce an equal, if not greater effect upon the crops, though they would not be of such permanent value. For if the burning did partially carbonise the bones, the carbon would take up the ammonia, for which it has considerable affinity, and give it off only on the application of excessive moisture. Bones thus burnt may therefore have even a more apparent influence on the first crop, and in its early stages, than unburnt bones; but this rather confirms than invalidates the opinions stated above.—*W. E. N.*

ON MINERAL & INORGANIC MANURES.—No. V.

By Professor Charles Sprengel.

(Translated from the German.)

As it is useful, for reasons which every one may easily guess, that lime should be intimately mixed with the furrow-slice, it is generally brought on the fields during a summer fallow, after which the land is planted in the autumn with winter crops, Wheat, for instance, Rye, winter Barley, Spelt, Rape, &c. The use of lime on fallows is the more necessary, the greater the number of the crops that have been taken off the land. Lime, however, is also very often used for summer crops, viz., for Beans, Vetches, and Peas, which plants require much lime, and are therefore much benefited by it. The Peas grown after being manured with lime have the property of boiling better, and of being nicer to the taste than those grown after dung; the same is the case with Peas grown after the application of marl. We may assume that this property is derived from the nature of its component parts, and limed or marled Peas will probably contain more starch than dunged Peas, the latter on the other hand more *legumen*. Lime, moreover, is useful with other crops also, in producing more starch, whilst dung will promote the formation of nitrogenous substances, such as the legumen in Peas, which does not become soft after boiling; whilst starch, on the other hand, swells and softens the other component parts. This subject being interesting as respects the physiology of plants, shall be more closely adverted to.

If a Potato crop is manured with lime, the roots become not only much more mealy, but more savoury; because lime will not only neutralise the acid of the tuber, but may even form some saccharine matter in them. Again, it is not advisable to manure Flax with lime, to which it will impart a less tenacious and coarser fibre. In Belgium, where they know more about the growing of Flax than anywhere else, it is only after a lapse of seven years subsequent to the application of lime, that it is ever planted on the same field. Still less is the growth of Buckwheat improved by lime, although its ripening may be accelerated thereby. I have found by experiment that 300 lbs. of lime per acre will cause it to ripen eight or ten days sooner than usual, which will be of importance in soils where Buckwheat grows too luxuriantly, or where it continually flowers without forming any grain. Rape will grow exceedingly well after a joint manure of lime and dung, but in this case, only the half of the usual quantity of lime is to be used; and it will also be best that the lime should be well harrowed in, which will prevent it coming into close contact with the dung, which is important for reasons previously stated. All sorts of Cerealia manured with lime will be conspicuous for their grain having very thin husks, and being very heavy and mealy, but there will be less straw than after dung, and it will scarcely ever be laid down. After manuring with lime, the stubbles are generally so clear of grass that they will afford but a poor pasture for sheep, on which account lime manure has often been rejected, but without sufficient ground.

It is to be regretted that the present high price of burnt lime often prevents its application on a large scale, but wherever this does not hinder it, the application of lime should not be neglected, as all fodder, as well as straw grown on it, will be nutritious and wholesome. We have stated so many advantages to be derived from it, that lime must reach a very high price indeed, before its use will cease to be advantageous.

Respecting the quantity of lime which is to be put on a certain area, it is to be observed, that sandy soils require much less than heavy ones, 300 lbs. per acre is generally sufficient for sandy soils, whilst stiff clayey soils will bear 5000 lbs. In England, where burnt lime, on account of the cheapness of fuel (coals), is not dear, even 10,000 lbs. are applied to an acre. Marshy soils generally require a large quantity of lime, still the effect is not always favourable, as this sort of soil is not only deficient in lime, but also in many other mineral substances, which are absolutely necessary for the growth of plants, as potash, silica, gypsum, &c. The application of lime will produce the greatest effect on marsh land, which is very natural, as it will find there much of the coal of humus ready for decomposition, and it will also be beneficial by changing the protoxides of iron and manganese, which are very abundant in such soils, into perfect oxides; the former being very noxious, the latter advantageous to vegetation. It kills also all insects, which are plentiful in new marshes, and increases thereby the amount of manure. On account of all these reasons a heavy liming will be required, and according as the soil is loamy, clayey, or sandy, 1000 to 1500 lbs. per acre are to be used. A soil which has entirely run wild and has been exhausted, requires also a strong lime manuring, but it must be soon followed by dung, else the ground will become absolutely useless. It may be put down as a general rule, that the amount of lime must be the greater the more clayey the soil is, the more iron it contains, and the more carboniferous and resinous the humus contained in it is. In fine, lime will act beneficially only where the soil has been previously well drained, which may be caused by the lime forming, in that case, with the sand a sort of mortar, which being insoluble in water, can produce no effect.

In some countries, lime is also used along with wood-ashes, which, as can be easily understood, must produce a very beneficial effect, for wood-ashes contain all the mineral substances necessary for the nourishment of plants, as we shall hereafter see. For this purpose, the lime is placed in a heap, sprinkled over with a little water, and immediately covered with a thin stratum of ashes; the lime gradually slakes, swells, and becomes visible in some spots, after which the heap is stirred through, sprinkled with water, and again covered with ashes, and after the lime has again become inflated, the whole is stirred and worked up. This sprinkling with water, covering with ashes, and working up, is repeated until all lumps of lime have disappeared, and the whole presents a homogeneous pulveriform mass. That such a mixture of lime and wood-ashes will be more active than pure lime, may be expected, because besides caustic lime, it contains also caustic potash (which latter has been formed by the action of the lime upon the carbonate of potash of the ashes), and which affects the vegetable remains and the coal of humus more powerfully than caustic lime, and produces from it humic acid after the lapse of a few hours. If the wood-ashes contain also sulphate of lime (as is the case at times), gypsum also will be produced. In order that the caustic potash thus obtained may not attract the carbonic acid of the air and become mild, the mixture is to be used as soon as possible, but always merely on fields which are not yet sown, else the alkali would act very detrimentally upon the plants. At times, instead of wood-ashes, peat-ashes are used, in which case, however, no such useful mixture will be obtained, as the peat-ashes are always deficient in carbonate of potash. Peat-ashes (as we shall see hereafter) act merely by their containing gypsum, common salt, phosphate of lime, and magnesia; at times, also, by an admixture of sulphate of potash.

(To be continued.)

CULTURE OF THE LAND FOR WHEAT.

When land is ploughed only to the depth of 3 or 4 inches, the active soil is so very limited, that the least change in the weather is injurious to the plants growing on it. The manure which is always applied to the Wheat crop under this system of shallow ploughing forms a layer near the surface; the roots of the plant ramify only through the furrow-slice in which the dung is placed, and consequently the plant has but little hold of the ground. It is thus that in severe weather in spring, the plant gets "thrown out," as it is termed, by the frost. The roots having spread out horizontally near the surface are easily exposed to the weather, and whether it be mild or frosty, dry or damp, are entirely under its influence: in a dry season the shallow soil and the manure in it become parched and inactive; in wet weather the roots having but little hold of the ground, a soaking rain and a little wind loosen the plant and it is blown out. Wheat sown on a deeply-cultivated soil, exerts the whole of its energy, at first, in the

production of roots. These strike deeply in the soil, filling the whole of it, with their minute fibres. The plants may appear thin during winter and in spring—those which turn out the best crops often have this appearance then—but, whenever genial weather comes, the organs of the leaf being highly excited, are prepared for vigorous and luxuriant growth; and a wide field having been laid under contribution for the purpose, the roots easily provide the nourishment required to support them under it. If a plant in such a condition be pulled up,—if the soil be deep, it will be found to have sent out its roots as minute fibres, 18 or 20 inches from it, in all directions; it is evident that no variations of weather can affect it, situated thus; it draws its nourishment from sources beyond the influence of the variableness of external agents. Thus deep cultivation, by encouraging depth of rooting, *indirectly* effects for the plant a comparative independence of the weather; but it has a *direct* influence in the same direction, for if the weather be wet a great depth of soil readily absorbs the water and conveys it down to the drains; and if it be dry it retains for a longer time a sufficiency of moisture. Of two crops of Corn, equally luxuriant in their growth, that is not so liable to lodge which is grown on the deeper soil, for its growth has been more gradual and natural, and less the result of artificial excitement. The manure in the shallow soil has not had its rankness rectified by mixture with a great mass of earth, and Wheat grown upon it will spring up rapidly but without rigidity; and though it may at one stage of its growth look more luxuriantly, it will at another yield less abundantly than a neighbouring crop which has throughout grown slower and generally promised less. Of course it must be understood that deep cultivation can be safely entered upon only on soils that are naturally or artificially dry. And now a few words as to the depth at which Wheat ought to be planted. We think this has not yet been satisfactorily determined. Nature ought to be our guide in things of Nature; she always drops her seed on the surface; and when it is necessary that any particular seed should get deeper than its natural gravitation would enable it, she provides them with means for the purpose. Thus the Barley and Wild Oat have awns, or beards, by which every motion of the seed pushes it forward; such a seed, lying on the ground, assisted by the wind, very soon wriggles itself beneath the surface. We think, therefore, that the nearer the surface a seed is planted the better, provided it be placed deep enough to protect it from its enemies, the birds, &c. This conclusion at which we arrive is strengthened in reference to Wheat by another circumstance; for, if a Wheat-plant be observed in spring, it will be seen that at whatever depth the seed was originally planted, the lateral roots which it has sent out to supply it with nourishment are always sent out from it at a point not far below the surface, certainly not more than one inch below it.—*John Morton, Chester-hill, Stroud.*

ON GORSE, AS A WINTER FOOD FOR HORSES.

In these times, when the diminished prices of Agricultural produce demand a rigid application of a judicious economy to every expense of cultivation, there is none which requires closer attention than that large item of expenditure—the keep of horses; and yet, because it is not actually paid in hard cash, farmers are in general very careless about it.

The Harleston Farmers' Club have shown in a strong light the necessity of attention to this important point, in the fact, that, when a discussion was raised upon it in the Club, it appeared that a body of excellent managers, in one of the best-cultivated counties in England, upon the same description of soil, and using the same breed of cart-horses, differed in their estimates of the cost of maintaining them by as much as fifty per cent.!

In a recent Number of the "Journal of the Agricultural Society," the experienced Mr. Rodwell has shown at how cheap a rate horses may be kept in the summer by means of that invaluable plant, Lucerne, upon soils, and, it should be added, under a climate, adapted to its growth; for I believe it is a plant which has not been found to thrive in the north of England.

Mr. Rodwell describes the soil on which he cultivated Lucerne with so much success, as a sand upon a subsoil of dry sandy loam. I have always understood that it requires the presence of a considerable quantity of lime. In Kent, it flourishes in deep light soils abounding in calcareous matter, and resting on the chalk. From the geological relations of Mr. Rodwell's land, I should conclude that it likewise contains a considerable proportion of calcareous matter, derived from the subjacent chalk. This view is confirmed by a reference to Dr. Daubeny's table of the constituents of crops, founded on analyses, which, if not all that could be desired in point of accuracy, may be regarded as a good first approximation, and the best guide which we at present possess in these matters. It appears from that table that the quantity of lime contained in a given weight of Lucerne is much greater than that contained in the same weight of red Clover. Of the last, 100,000 lbs. contain 584 lbs. of lime; while the same weight of Lucerne contains as much as 1304 lbs. I have seen Lucerne grow very well for a number of years on the non-calcareous soils of Middlesex, which were prepared for it by a dressing of lime or chalk.

There is another plant to which I wish to draw attention, as a food for horses in the winter, which flourishes most on sandy and gravelly soils—it is not necessary that they should be calcareous—but which is hardy and indigenous, and not very limited in its range either of soil or climate in Great Britain and Ireland. This is the Ulex Europæus, the common Furze, Whins, or Gorse.

Botanists make three varieties, or sub-species; two of them, U. Europæus and U. nanus, or dwarf Furze, may be seen on every common; the latter is the most abundant, the former is that best adapted for the food of horses and other cattle, and is the only one of the two worthy of cultivation. It is distinguished from the dwarf Gorse by its more vigorous and bushy growth, rising to the height of from 2 to 5 feet, as well as by the greater succulency of its young shoots. The U. nanus does not attain half this size, and is minuter in all its parts.

A third sub-species, or variety, is the U. strictus of Mackay's catalogue of Irish plants. It was discovered by Mr. J. White, in the park of the Marquis of Londonderry, in the county of Down, and is now well known in our gardens as Irish Gorse. It rarely flowers, but is readily propagated by cuttings. It is easily distinguished from U. Europæus by its smaller size, its dense and compact, rather formal mode of growth, and its upright branches, which are so soft and succulent that sheep and cattle are extremely fond of them; and Mr. Murray, of the Glasgow Botanical Garden, strongly recommends its cultivation for early spring feed. The species, however, which is actually cultivated in some districts for fodder is the U. Europæus.

The Gorse is not indigenous to Sweden, and Linnæus is said to have fallen on his knees in a transport of delight, when he first beheld a large extent of Heath glowing with its vegetable gold. Such a prospect, in the spring, is one of the most exhilirating which I know. Goldsmith has done homage to its beauty; but in his

"blossomed furze, *unprofitably* gay"

has greatly maligned its utility; for a more valuable plant, as a food for horses and milch-kine*, does not exist—to say nothing of its use for fuel, the only purpose for which it is cultivated in the south of England, except as a cover for foxes and game.

In the northern parts of the island, and in Wales, its value as food for horses has long been known; and during the Peninsular campaign, when our cavalry were suffering from want of fodder, some of the troopers who came from those districts cut and bruised for their horses the Gorse, with which the wastes of the country abounded; and the animals were found to thrive so much upon it, that the practice was generally adopted in the Army during the rest of the campaign. In consequence of hearing of this fact, my father proposed to sow a few acres of the poorest part of a farm which he then held with Gorse, as a winter-food for the horses; but my prejudices were against the plan, and I had sufficient influence to prevent its adoption. It was only subsequent experience of its use in Wales which convinced me of its value as a winter-food for horses. I have heard, that when properly bruised, it is equally good for cows, and produces very sweet butter; but on this point I do not speak from experience.—*J. Trimmer.*

(To be continued.)

* It has only recently been applied to the latter purpose. At Birmingham, I have been told that a dairy of 200 cows is fed exclusively with it in the winter.

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. IV.

(Continued from page 37.)

The next part of the process consists, after bruising the soil gently in the mortar, to pass it through a fine sieve which will retain a Mustard-seed. What remains in the sieve must be carefully weighed and noted down under the head of "coarse sand and undecomposed vegetable fibre."

The powder which passed through the sieve must now be placed in a clean porcelain crucible, boiled for five minutes with about two ounces of distilled water, being stirred during the process with a glass rod, so as completely to divide the particles of soil.

While hot, the contents must be quickly poured into a small narrow glass vessel (a half-pint glass measure will do very well).

In about one or two minutes the contents of the vessel will be found to have divided into two portions; the fine sand will, by its weight, have fallen to the bottom, while the impalpable matter remains dissolved in the water. This supernatant liquid must be carefully poured off into another vessel. If any of the sand has passed with the solution, which is generally the case, it will speedily sink to the bottom, when it can be removed by repeating the process of pouring off.

The vessels containing the sand must now be washed with cold water, and the contents brought into one vessel, at the same time carefully place the solution of impalpable matter on one side, for further operation presently.

It is not possible by this single operation to separate the sand from the powder completely. A little practice and tact will, however, enable any one to separate the two completely, by washing the sand frequently with cold water. This is done by adding a small quantity of distilled water, and shaking the vessel quickly, and at the proper moment pouring off the washing. The water thus used must be added to the solution containing the powder. When the washings remain clear after agitation with the sand, the operation need not be repeated, as it is now free from impalpable matter.

The sand thus separated must now be carefully dried in a clean porcelain crucible, over a spirit-lamp, and then weighed, and the amount noted down as "Fine Sand."

The process of washing and separating the sand from impalpable matter is most difficult with heavy soils; it is not at all so with light specimens.

The next part of the process is very simple. The solution of impalpable matter must be poured into a glass funnel, previously charged with a filtering paper, which has its weight marked upon it. The powder thus collected must be carefully dried, and its weight, after deducting that of the filter, noted down as "Impalpable Matter."

The amount of carbonate of lime in any soil is easily obtained, as follows:—

The coarse sand sometimes contains small lumps of chalk, but unless the soil is "chalky," the amount is inconsiderable in this part of the analysis. There will be no chalk found in the "Fine Sand." It must be sought for in the impalpable matter.

For this purpose, take 50 grains, and dissolve it in a solution of nuriatic acid and water (about half a dram of acid to a dram and a half of water), and set the solution aside for two or three hours. Then add an ounce more water, pass it through a marked filter, and dry as above. The loss in grains, after deducting the weight of the filter, will give the amount of carbonates (which are generally chalk) in the 50 grains operated upon, from which its proportion to the whole soil can easily be calculated.

The process of drying alluded to above is best done by a sand or water bath; where these cannot be obtained, it must be done in the porcelain crucible; but great care is necessary, in thus conducting the process, to prevent the contents from being charred by applying too much heat.

The animal or vegetable matter in the soil can be easily known by exposing a given quantity of the impalpable matter, say 50 grains, to a red heat in a Hessian crucible. The loss will give the requisite result. The oxide of iron and gypsum require a more complicated analysis, which can be found in chemical works.

For all ordinary purposes, however, the analysis has been now carried far enough. The information thus gained is extremely interesting to the farmer. A little practice will render the operations perfectly easy; no chemical knowledge is requisite. A determination to avail himself of the knowledge thus to be obtained, a tolerable share of patience, and the exercise of ordinary tact, will be all sufficient. The method is similar to that described by Sir H. Davy.

The paper of the late lamented Mr. Rham upon the same subject, in the "Agricultural Journal," is well worthy of perusal. My principal objection to it is the indefinite application of the terms clay and humus.

The table of M. Thaer is still more ambiguous. The term clay is incomprehensible as an element of Chemical analysis. The less "impalpable matter" in a soil, the more sand will be found, and *vice versâ*. Clay is, in fact, "impalpable matter," and water with an excess of aluminous earth.

By the simple process I have described, then, the farmer will obtain in a very short time the following information about his soils:—

1st, Amount of moisture, showing the capabilities of the soil in retaining or parting with this important element.

2d, The amount of coarse sand, gravel, or undecomposed vegetable fibre.

3d, Fine sand, without which no soil is fertile.

4th, Impalpable matter, which is of the utmost importance, not only as containing the principal inorganic elements in the food of plants, but as having a most important bearing upon the fertility of soils, in the proportions in which it exists to that of the sand.—*C. R. Rree, Stowmarket.*

(To be continued.)

Home Correspondence.

Shed-Feeding Sheep.—My attention has been given to the Leading Article in your publication on the 13th inst., in which the subject of Shed-feeding sheep has a prominent place. I am not at all surprised that Mr. Childers has ascertained by actual experiment that "the sheep in the shed, though they consumed nearly one-fifth less food, made above one-third greater progress" than those which had been folded in the field. Shelter and warmth to all animals when fattening are most essentially important, and I have no doubt that the farmers who fold their sheep on open Turnip-fields in cold wet weather lose considerably by doing so, and would find their advantage (without our dwelling on the cruelty of the prevailing contrary system) in providing such cheap and easily-formed shelter as you have recommended. It is not long since I have seen sheep in the south of Scotland, during the most penetrating rain and snow storms, up to their knees in the mire of a clay field, which was almost bare of Turnips, and without the possibility of obtaining greater shelter than the wet ditch of a leafless hedge three feet high afforded them; there they lay cowering from the pitiless blast in misery, from day to day. And this was the systematic treatment pursued there towards store-sheep, with hardly an exception. The loss sustained in the comparative waste of manure, and in the condition of the sheep, by not taking to them Hay and Turnips, in covered sheds with yards during the severity of weather, is inconceivably great. But "the opinions of any agricultural correspondent, however safely built upon facts, are not (as you have judiciously stated) necessarily of general application, because that which is fact in his neighbourhood may not be fact elsewhere." What may be the best treatment for Leicester Hogs put up to fatten in a district where Turnips constitute the principal winter and spring food, may be totally inapplicable to other varieties of the species, under other circumstances of age, habits, soil, and climate, even within the limits of the same county or province. There are many breeds of sheep, for instance, which require, from their nature and peculiar habits, a constant liberty of range and free ventilation, and many localities in which they would nearly starve if they were restricted from roaming about, without any other means of obtaining shelter than the lea side of a hill or furze-bank, or stone wall. I shall suppose the case of the

blackfaced or Cheviot sheep; these, if confined in warm houses, would be injured in health, and after a few generations, rendered so delicate by the natural transmission of new habits, and even of physical conformation, as to be unfit for their native pastures. Those nomadic tribes accustomed to brave the wintry blast, and scrape up their scanty food from under a covering of snow, would become diseased, or perhaps die of *ennui*, if confined in close sheds and fed luxuriously. The Cheviot sheep farmer well knows that the healthy condition of his flock is preserved by their being kept out on the hills as long as a blade of grass can be cropped from the ground, and he is unwilling to divide among them even a few plaid-fulls of the bog hay which has been cut and stacked for them near the stells, as long as they can procure any food for themselves, lest they should become indolent and lose the robust vigour which active exercise imparts to them. But some shelter is necessary for the mountain sheep, of which countless thousands have at different periods perished from the want of it. Until stells were built to save them from snow-drifts, there often was no chance of saving them from being smothered in heavy snow-storms, but mere rain, or even cold wind, unaccompanied by much snow, are not dreaded if their range permits them to obtain the shelter of a hollow, or even of a hill-side on which the wind does not blow: necessity alone causes them to enter any of the numerous stells, which the good sense and humanity of the late Lord Napier, and other land-proprietors in Scotland have so liberally built, where the eddying winds are least likely to affect them. Sheep, like those in the hill districts, would feel a sense of suffocation if they were inclosed in a covered shed within a close country; and I think that all flocks, except the individuals of them which are actually fattening, enjoy more health in the open air, but with liberty to rest under some natural shelter, or such artificial shelter as consists with their liberty of movements, from wind or rain than if housed. For ewes in young, air and exercise and perfect freedom seem to be most necessary; but whether near the mountain or in the inclosed vale, an hospital should be provided for the sick, a small park for the tups, an inclosure for lambing and feeding-sheds, such as those represented in your plate to some extent. In short, the principle of affording shelter to sheep is most just and necessary; though confinement in sheds is unsuited to the nature and condition of the hardy varieties, which depend on their fleecy great coats for warmth, and which, if shut up in a warm place in their dripping raiment, would emit morbific evaporations. High-bred Leicesters, or other lowland sheep of the same indolent habits (comparatively with the mountain tribes) are only suited by their nature to lowland districts, where hedge-rows and plantations usually afford sufficient shelter, except in extremely severe weather; and therefore, except for the purpose of accelerating the process of fattening or sheltering flocks of sheep where there is not sufficient Grass-land for their keep, as in many of the purely tillage farms of Great Britain, thatched sheds may be altogether dispensed with. You perceive, Sir, that my exceptions in favour of your system are few, and only such as any practical sheep-farmer would admit to be reasonable.—*Martin Doyle.*

Shed feeding of Sheep.—I am perfectly satisfied of the fact, so fully proved by Mr. Childers' valuable experiments, and dwelt upon in a late Number of your Paper, that sheep fed in sheds will produce much more mutton in proportion to the quantity of food they consume, than others allowed to go at large in the open field, exposed to all the variety of weather, and induced to take much more exercise. I have tried such experiments myself, and occasionally with much success; frequently, however, the whole advantage has been thrown away at the end, by the sheep being attacked—as they are very apt to be when confined for a length of time upon litter, which will hold a good deal of moisture, though often renewed—by a disease in the feet of so painful a nature, as to cause them to lose more flesh before it can be cured than they will recover in a month afterwards. The disease is the same, though I think more virulent, owing, perhaps, to the higher feeding to which the animal has been subjected, as that known by the name of foot-rot, or foot-halt, common to sheep fed in rich pastures, and in damp seasons. This circumstance is a great objection to the mode of feeding sheep in my case, and it may be presumed to be so in others; and it is desirable to know both how the evil may be prevented and cured.—*John Grey, Dilston.*

Sprengel on Inorganic Manures.—As your Paper is not intended for Chemists, it is requisite that the facts which it professes to give should be accurate and clearly expressed. The translation of Sprengel's lecture on Mineral Manures in your last No. (Jan. 20) is, I fear, wanting in both these essentials. Take the following specimens:—"By the action of quicklime, organic matter is converted chiefly into humic acid. To this, lime bears a strong affinity, and if previously combined with water it will lose it again through the above combination; the new compound, however, will again combine with water." Now to say that lime bears a strong affinity to humic acid, means, if it means anything, that it bears a strong resemblance to it, and no doubt it would be so understood by nine-out of every ten of your readers. The sentence might, perhaps, have been more intelligible thus:—"By the action of quicklime, organic matter is converted chiefly into humic acid, with which the lime then enters into combination, forming a humate of lime, it having a strong affinity for that acid." The next paragraph is full of inaccuracies. We are told that caustic lime is soluble in water, "but 752 lbs. of water at 168° Fahr. are required to dissolve 1 lb. of calcareous earth." Now, according to Dalton, 750 parts of water at 60° are necessary to dissolve 1 pint of lime, and, which is a remarkable fact, the hotter the water the less lime it will dissolve; so that at 212°, 1280 pints of water are requisite. But why take the temperature 168°? What the farmer is chiefly concerned in is the solubility of lime at an ordinary temperature, 60°. And why use the words "calcareous earth?" by which he evidently means pure lime, though most people would think he meant limestone, or earth containing a quantity of carbonate of lime. He goes on;—"It (lime) is easily soluble in water if free from carbonic acid, and to this its action on the organic matter of the soil is owing!! In order that substances may act upon each other, one at least must be in a liquid state, and this explains why caustic lime dissolved in water will injure vegetation." Is a farmer to understand, then, that a heap of quicklime thrown on a grassplot would not kill the grass, but that watering it with lime-water would? The truth, probably, is, that quicklime destroys vegetable matter, (*i.e.*, causes the element to form new combinations), owing to its affinity for water and acids, and therefore, when mixed with vegetable matter it converts the oxygen, hydrogen, and carbon chiefly into water and humic acid. —*Crito.* [Probably the error of naming 160° as the temperature at which 1 of lime is soluble in 752 of water, was owing to the figures in the original being mistaken for centigrade degrees, and so reduced to those of Fahrenheit's scale.]

Experiments with Various Top-Dressings.—The following experiments were tried upon a mixture of equal parts of brick-clay and sand. The clay was dug from 20 feet below the surface, and clean white sand was intimately mixed with it, and the whole was put into beds upon a surface of white clay, each partition being carefully divided. Barley was sown on the 5th of March, and the top-dressings were applied on the 15th of April, as per Table, to each partition,—with the intention of its being in a manner a key to experiments with the same kinds of manure, sown, in the same proportions, in the field, in square rods and chains. The object of these experiments was to ascertain whether certain salts, &c. were mere stimulants or manures. There being no animal or vegetable matter in the mixed brick-earth and sand in the beds, if any effect resulted from these applications, the manures must be of a positive character; but a perusal of the following will give an idea of their relative effects, both upon the pure earth and upon the arable land:—

Manures.	Quantity, at the Rate of per Acre.	Value of Samples, from the Artificial Soil, per Quarter in the Market.	From the Natural Soil. Calculated Produce per Acre. Good Corn.	Off-Corn.	Value of the Sample per Q. in the Market.
	lbs.		qrs. bsh.	qrs. bsh.	
Nitrate of Soda	160	23s.	7 4	2 6	27s.
Saltpetre	160	34	7 4	— 1	35
Carbonate of Ammonia	160	35	5 5	— 3	—
Muriate of Ammonia	160	35	6 2	— 3	35
Guano	3 cwt.	—	6 2	— 4	35
	bush.				
Kiln-dust	40	32	5 7½	— —	—
Pale Malt-dust	40	35	6 2	— —	—
High-dried do.	40	35	5 5	— —	—
Wood-ashes from Kiln	40	—	5 0	— —	—
	cub yds.				
Red-burnt Earth	80	28	— —	— —	—
Black-burnt do.	80	35	— —	— —	—
Earth without dressing	—	32	5 0	— 4	35

It will be seen from the above that the results were similar, both as regards the bed of brick-clay and upon the field. The sample of the produce from the saltpetre upon the field was superior to any of the others, having less proportion of offal. The produce of the nitrate of soda was very inferior, with an enormous proportion of off-corn; this proves, so far as we can judge from so small an experiment, that it is unfit for Barley on clay-lands. The superior produce from the pale malt-dust, in comparison with high-dried or kiln-dust, justifies the idea that a large proportion of its manuring qualities are carried off by the application of too much heat. The superiority of the produce of black-burnt earth over the red is worthy of notice, as it was undoubtedly upon account of preserving its charcoal; ashes, containing much charcoal, from paring and burning the surface only, are in all cases superior to the red or mere burnt earth, it being destitute of charcoal. If means could be adopted for burning in a temporary furnace covered with a sheet-iron, in the same manner as it is prepared here in making pot-mould, by merely scorching the turf from which a rich compost is made for strong-feeding plants, it would open a new field for the employment of our labouring poor. I am convinced in the common manner of burning, too much heat in the fires is required to allow the charcoal of the plants to be preserved. Considerable caution is necessary in the application of saline manures; the evil effect of nitrate of soda is visible for several years in the working of heavy clays; but saltpetre is less so than the nitrate, as is muriate of ammonia less so even than saltpetre, and it likewise produces a kinder growth than either, being more like pale malt-dust in its effect. I am informed it may be purchased at the wholesale houses at the same price as saltpetre. There is certainly an imitation of Nature in the application of saline manures, or how is it that the fens of Lincolnshire, the hundreds of Essex, the Channel Islands, and the flats of Holland, are so much superior in fertility to soils of the same mechanical texture in the interior of the country at a distance from the sea?—or that animals fatten so much quicker upon the alluvial lands reclaimed from the sea?—or that they pine and die in the interior of America if salt is not often given them?—or that Sea-weed, where it can be procured, is a universally powerful manure? It is not a solitary experiment, either upon a large or small scale, but a multiplicity instituted upon various soils, and in various seasons, the climate, in respect to distance from the sea, altitude, &c., being taken into account, which alone can inform us of the truth in these matters.—*John Rivers, Sawbridgeworth, Herts.*

Tests for Manures.—The season is now approaching when artificial manures will be applied to the land; and I think you cannot render a better service to the Agricultural portion of your readers than by pointing out a mode by which the purity of each kind may be sufficiently ascertained by the farmer for practical purposes. It is a matter of the highest importance to the welfare of Agriculture that the general use of artificial manures applicable by the drill should not be impeded by the frauds which are continually practised by dishonest dealers. I feel persuaded that the produce of the land may be immeasurably increased, and at a much less cost than at present, by the use of the manure-drill and horse-hoe; we need hear no more of worn-out soils; and the cleanliness of cultivation resulting from their use will, if not entirely supersede the necessity for fallowing, at least materially prolong the interval. Farm-yard manure, though undoubtedly containing all the necessary food of plants, also contains the seeds of all pernicious weeds, under circumstances most favourable to their germination. By great expense in preparation, and submitting to great loss of manure in the process of fermentation, such manure may be delivered on the land free from the seeds of weeds, but the cost much exceeds what most people imagine, and what the same degree of fertility may be produced for by means of artificial manures applied by the drill. A very great advantage arising from the use of the latter is, that on heavy land they may be applied at the most favourable moment without the expensive, long, and injurious process of kneading it by the haulage of farm-yard manure in damp weather, thereby producing not unfrequently sterility rather than fertility. I am well aware that the efficiency of artificial manures containing only two elements can only be reasonably calculated upon after an accurate analysis of the soil to which it is proposed to apply them, and that much disappointment has arisen from the want of such caution; but I am anxious that my brother farmers who intend to purchase artificial manures shall have the means of testing by a simple process whether they receive what is proposed to be sent them or something wholly different.—*A Farmer.* [We have some matter in preparation with reference to this certainly very important subject, and no time will be lost in publishing it. But the task is one of great difficulty and in part insurmountable; for who is to be alive to the ever-varying devices of fraud, where there is a desire to practise it. Moreover, it is not even easy to give plain and simple rules which farmers can employ. We gave formerly a ready and simple test for common salt in nitrate of soda; but we never heard of any one making use of it. So long as farmers will attempt to buy manures *cheaper than they can be made*, frauds will be practised. Dishonest men are always to be found ready to cheat under the pretence of selling cheap, especially when it is so easy to lay the failure of such agents as manures at the door of Chemistry. If a fair price is paid, and only venders of known respectability employed, there will be no fraud.]

Phosphoric Manure.—I have received two or three letters requesting me to state in your Paper the composition of the phosphoric salts used in the experiments upon Turnips. The following is the composition:—The phosphate of potash, soda, and magnesia, weighed about 80 lbs. per bushel, and contained about 50 to 60 per cent. of the pure salts, the residue being sulphate of lime. The phosphate of ammonia was in crystals, and pure. The superphosphate of lime weighed 75 lbs. per bushel, and consisted entirely of superphosphate and sulphate of lime, and no free sulphuric acid. In my experiments on unburnt bones given last week, it is important to remark that the bones were quite pure, reduced by grinding to a powder, and sifted through a muslin sieve. This accounts for the action of sulphuric acid not being so much superior. Repeated experiments with the bone-dust of commerce have satisfied me that on my soil it is quite useless. —*J. B. Lawes.*

Sea-weed as Manure.—I beg to inform your correspondent "M.T.," in reply to his inquiry in your last *Gazette*, that I do not live near enough to the sea to avail myself of the weed as a manure, but I have conversed with farmers who are in the habit of using it, and their account is, that for a single crop it answers well, but that it seems to melt away in the earth. Nevertheless, the repeated use of it must, in the end, materially affect the staple of the soil; for, besides a great multitude of animalcules and small crustacea always entangled in it, a considerable quantity of inorganic substances must be thus accumulated, for it contains potash, soda, sulphur, lime, and magnesia; from this last, indeed, there may be some danger, if carried to excess; for every pint of sea-water contains about 40 grains of magnesian salts, and this earth in large quantities is known to be injurious. The Sea-weed is seldom carted before decomposition has begun, because the quantity of water which it contains when fresh adds so much both to its weight and bulk; and before that process begins it would be useless.—*L. Vernon Harcourt.*

Societies.

AGRICULTURAL SOCIETY OF IRELAND.

At the Council Meeting, on Thursday, January 25th, the Secretary laid on the table the list of Members of the

Society for 1843, and also a copy of a circular letter, to be addressed to the Secretaries of the different local Farming Societies now in connexion with the central one, and amounting to one hundred in number, calling on them to furnish the names of such Members as were common to both bodies, and also to inform the Council how they proposed to qualify for the Society's premiums this current year, pursuant to the resolution to that effect, which was passed at the last general Meeting of the Society; namely, That each local Society, to entitle it to the premiums of the Central one, should have five of its Members at least, also annual Members of the other Society, or that a sum equivalent to five annual subscriptions of one pound each should be contributed by the Members of the Local body, to the Central Society each year. The Secretary stated, that the beneficial effects of that resolution were already most sensibly felt. Many of the proprietors in the different local societies, from which, hitherto, only one pound, and sometimes no subscription at all, was received, have begun to look up, in order to qualify the local society in time for receiving the premiums of the central body this year. Upon the motion of Mr. William Blacker, it was resolved, that the noble Chairman of the council, the Marquess of Downshire, be requested to communicate with the council of the Royal Agricultural Society of England, and of the Highland Society of Scotland, upon the subject of establishing a uniform system of weights and measures throughout the United Kingdom, for the sale of all agricultural produce. The Secretary having brought forward the voluminous reports upon thorough-draining, from the different proprietors in Ireland, who were competitors for the Societies' gold medal, it was suggested by Mr. Blacker, and agreed to, that the Secretary be directed to write to the different competitors to ascertain from them the beneficial effects that have hitherto arisen from any previous experiments made by them in that department, or from any other experiments in draining, instituted by them previous to those in question. These reports were prepared with the greatest accuracy, and framed as they were from undertakings commenced upon an extensive scale, in different parts of the country, afforded some of the best and most valuable information, not only upon the subject of thorough-draining in general, but also upon the price of labour and other statistical information in various parts of the country. A letter was also read from the Marquess of Downshire, chairman of the council, stating his regret that the city of Kilkenny was not fixed upon for holding the next great annual meeting and cattle show of the Society, and expressing a hope that it was not too late to reconsider the matter. Letters were also read from Professor Kane, inclosing some copies of the paper on the growth and cultivation of Flax, read at a late meeting of the Royal Irish Academy. Letters and reports were also read from the Agricultural Society lately established in Jamaica, seeking for the co-operation and correspondence of the Central Society.

Miscellaneous.

Scottish Agricultural Chemistry Association.—The objects of this association have now been fully and positively defined in consequence of the success of the subscriptions necessary for carrying their views into effect; and as its operations are on the very eve of actively commencing, through the instrumentality of their able and distinguished chemist, Professor Johnston, we think it is full time to submit, for the information of our readers, the following statement of the chief objects of the Agricultural Chemistry Association—the duties of the chemist—and the privileges of subscribers:—*Objects of the Association.*—1. The diffusion of existing information, theoretical and practical, by means of occasional verbal expositions, addresses, and correspondence; and 2. The enlargement of our present knowledge, by experimental investigations of practical Agriculturists in the field, and of the Chemist in the laboratory. *Duties of the Chemist.*—The Chemist will be expected to assist in suggesting such series of experiments as are most likely to promote the objects of the association,—to consider and explain theoretically the results obtained—and to point out how they may be best turned to account by the practical farmer. Before commencing the analysis of any substance submitted to him, the chemist may require a statement of the precise object which is proposed to be attained by it. He shall be bound to give only such an analysis as is adapted to the particular practical object for which it is required, and he will apprize the party of the charge to be made for it. The Chemist will have his laboratory in Edinburgh, but during a portion of the year he shall visit different parts of Scotland, on invitations, and at times approved of by the committee. A short journal must be kept by the Chemist of his proceedings, whether in Edinburgh or in the country, a record kept of all the analyses he makes and of any reports he may draw up—all of which, as well as the correspondence on the business of the association, must be patent to the committee of management. All applications for analysis or advice, are to be addressed to the Chemist. *Scale of charges.*—1. Testing saline manures, (such as gypsum, nitrate of soda, sulphate of soda, guano, bone-dust, rape-dust, &c.,) for adulterations, for each sample, 3*s*. 2. Examining limestones, marls, shell-sands, &c., to ascertain the proportion of lime, and the presence of magnesia and alumina, 5*s*. 3. Ascertaining the proportion also of the latter, or of any other ingredients, for each ingredient 2*s*. 6*d*. extra. 4. Examining a soil, or the ashes of a plant, to determine the proportion of one ingredient, 5*s*. The proportion of every other ingredient to be charged 2*s*. 6*d*. additional for each. 5. Examining, with a view to its commercial and Agricultural value, any artificial mixed manure (such as manufactured Guano, humus, animalised carbon, patent manures, &c.), 6*s*. 6. Examining the products of vegetation, to determine, for example, the quantity of water, or of starch, or of sugar, in Potatoes or Turnips; or of oil or gluten in wheaten flour, from 2*s*. 6*d*. to 5*s*. 7. Letters asking advice, unless accompanying, and in reference exclusively to substances transmitted for analysis, to inclose 2*s*. 6*d*. 8. No sample to be sent for analysis without the fee being inclosed with it. *Privileges of Subscribers.*—1. Every landed proprietor who pays 1*l*. yearly, and every tenant farming other persons' land, who pays 10*s*. yearly, shall, on subscribing their names, or authorising their names to be inscribed in a book to be kept for that purpose, be entitled to the services of the Chemist on the terms before mentioned. 2. Every 10*s*. subscribed by a tenant, or 20*s*. by a proprietor, will entitle to two analyses yearly on the above terms, and all beyond that number to be charged one-half more. To the numbers of letters of advice, it appears unnecessary at first to prescribe any limits or check beyond the small charge above stated. 3. The Directors of the Highland and Agricultural Society shall be entitled to publish exclusively, in their Transactions, the reports made to the general meetings of the subscribers, as well as such chemical analyses as in the opinion of the committee are deserving of publication. 4. Every Agricultural Society, by paying to the funds of the Association 5*l*. yearly, shall be entitled to one lecture from the Chemist; by paying 10*l*., two lectures; and by paying 15*l*. three lectures;—and such Society shall have the right to prescribe the particular subject of each lecture, as well as to have these lectures delivered either separately or together.—*The Fife Sentinel.*

The Nature of Soils.—"The study of the soils and of the rocks that lie beneath them has led geologists to conclude that the loose materials of which the soil is composed are derived from the solid rocks that lie beneath them—that there was a time when these rocks were everywhere on the surface; but that gradually, by the operation of the rains and other natural causes, these rocks have been worn down and disintegrated, till what had been solid rock became the loose materials which form the soil. These rocks are essentially of three kinds—limestone, sandstone, and clay or slate, the latter in various degrees of hardness; so that if you want to know the kind of soil in any given district, you have only to inquire into the nature of the rocks which form the substratum of that district. But, besides this, the physical examination of the soil tells a good deal of its nature. For instance, if you were to take a quantity of soil of a given weight, and pour water over it in a vessel, then allow a minute or two for the heavy particles to subside, and pour off the water with the lighter particles floating in it into another vessel, and repeat this till all the lighter particles were carried away, then again dry the heavy materials and weigh them a second time—the difference between the first and second weight of the soil would give the amount of the fertilising matter contained in the soil; for all the vegetable or fertilising substances would be carried off in the water, leaving the inorganic and unfertilising substances behind. Exactly the same result would be arrived at by heating a quantity of soil of given weight in an oven or other place—the vegetable matter would be burnt out, and the difference between the first weight and that of the residuum would be the amount of fertilising substances in the soil. These are rude chemical tests, but when you examine the soil by more refined analysis, you discover that there are eleven substances, every one of which are necessary for the growth of vegetation." This the Professor said he would dwell upon more particularly in his next lecture. He then referred to the subsoil and that part of the soil to which the vegetables did not usually penetrate. "Every farmer knows that a few years after he has limed the surface of his fields, the presence of the lime becomes gradually less and less, till it altogether disappears. Now, it happens that this lime is to be found sunk into the subsoil. So it often happens that the very substances of which the upper soil is most deficient are to be found in the subsoil. The cause of this might be easily explained, for when you consider the action of the rains, &c., you see that their tendency is to carry fertilising substances from the surface down to the subsoil. It becomes, therefore, a matter of importance to know whether it would be advisable to bring up the subsoil to the surface and mix the two together. This is not in every case advisable. For instance, here is a section of a soil 18 inches deep, which I have received from a place in Renfrewshire, the surface of which contains a certain quantity of fertilising substances, while the subsoil contains only half the quantity. It is clearly unadvisable, therefore, in this case, to do more than, by draining, to open up the soil, and let the roots of the plant draw from the subsoil that nourishment which it is capable of affording."—*Lecture at Edinburgh on the 10th January by Professor Johnston.*

Wasteful Management of Manure.—Some idea of this may be gained by analogy. Let us imagine that a farmer keeps three teams of horses, who consume, say two quarters of Oats per week. Let the farmer give one quarter each week to the horses, and dispose of the other quarter as follows:—There may possibly be some ruts in the road leading to and from his farm-yard; let him pour as many as possible of the Oats into every one of the horse-holes and ruts of this road, beginning at the gate of the yard, and proceeding to the nearest turnpike-road. There may seem much trouble in all this, but nothing valuable can ever be gained or done without trouble, and this experiment will probably always be conclusive. Some farm-yards are nicely drained, and very frequently the drains run into the horse-pond. Let the farmer insist on one of his labourers (who may possibly have some prejudice against it) pouring a good drill of Oats into every drain that leads out of the yard till it arrives at the pond, where he may throw in a bushel or so, and if the drain terminates, as drains sometimes do, on a hard road, let him leave a small heap of Oats in every black puddle. When he shall have done this, let him cause some of the Oats to be scattered in every direction round his stable, and take every possible precaution so that the birds of the air, the mice and rats of the field, the fishes of the ponds, and the creeping things of the earth, may come in for a share of the Oats. The farmer's neighbours may call him mad, but let him not mind this. Ulysses was formerly called mad for sowing salt, but now, many people sow salt who are considered sensible, and even clever. Let the enterprising improver keep perseveringly on with this practice for—say three weeks. On or about this period, the ribs of each of his three teams, when in single harness, will probably form a very respectable representation of a park paling. At this point it is time to pause, and seriously ask himself the question, whether it is wise for a man actually to facilitate the waste and destruction of produce which it has cost him much money to gain, and the economical management of which will produce more money. That which we have imagined it possible for a farmer to do with his horse-food, is not a whit more unwise than the practice of some slovenly farmers with respect to their Manures. What Oats are to his horses,—Manure, and especially the liquid and gaseous portions of Manure, are to his fields. Every atom of earth which comes into contact with his dung, preserves for it some of its fertilising virtues, yet he accumulates it in unpaved yards. Every breath of air that passes over it becomes the vehicle for carrying the volatile gases, in which plants delight, from the farmer's dung-yard to everybody else's field; yet he keeps it for a year uncovered with mould. Every drop of rain which falls from the heavens dissolves some of its most valuable portions, and conveys it into the horse-pond, or some of the neighbouring ditches; yet the good man never dreams of sinking a tank, in order to preserve a substance every pound of which Liebig tells us will suffice to grow a pound of Wheat. Nothing can show more clearly than this national waste, the necessity of men being made acquainted with the laws of Nature, which can never be transgressed with impunity, which combine to ruin every man who regards them not; whilst there is not one law amongst them which, if understood, may not be made the ready and willing instrument of his will.—*Maidstone Gazette.*

Importance of Co-operation between the Farmer and Chemist.—We believe that by far the greatest obstacle to the advancement of scientific Agriculture hitherto, has been the want of co-operation between the farmer and the chemist. Each has tried to move forward alone, and thus each has been led astray. We may not inaptly apply to them the well-known story of the lame and the blind, neither of whom alone could proceed with safety, but when united arm-in-arm, the defects of each were fully compensated for by the superior advantages of the other. Thus the farmer, from his knowledge of practice, is enabled to progress in any given direction, but, from his want of acquaintance with the fundamental principles of his art, may be justly considered blind; whereas the chemist, however clearly he may see the end to be attained, makes but a very lame progression, owing to his ignorance of practice. Let the two but consent to become mutually dependent, and, proceeding arm-in-arm, the assured step of the well-practised farmer will be guided in the right way by the clear-sighted knowledge of the enlightened chemist.—*Dr. Madden, on the Advantages of Extended Chemical Analysis to Agriculture.*

Ewes and Lambs.—A difficulty is sometimes experienced in making ewes own their lambs, and oftener, perhaps, when cases of twin lambs occur than at other times. Those who desire to rear all their lambs may find a benefit in sprinkling a little fine salt over the disowned ones. This will usually attract the mother, and when once the operation of licking has been performed, there is seldom any danger of desertion. A friend assures us he has practised this method with decided success, and no injury to the lambs may be apprehended from the application. Sheep, when about to lamb, should be moved and disturbed as little as possible, as all such disturbances, especially with young or wild ewes, greatly increase the probability of their forsaking their young.—*Ayrshire Agriculturist.*

Preparation of Stiff land for Turnips.—Every Agriculturist is aware of the difficulty, and, in some seasons, of the almost utter impossibility, of reducing strong adhesive clay soils to a state fit for sowing Turnips. A field on this farm, allotted for Turnips for the present season, is exactly of the description of the soil here referred to, and with the view of surmounting the difficulty experienced in preparing such a soil, Mr. Richardson directed that it should undergo a thorough autumn tillage. It was accordingly ploughed from stubble betwixt the 3d and 7th of October. Betwixt the 10th and 13th of the same month the drill's were opened, and farm-yard dung driven from the close, applied to it, at the rate of about 18 tons per Scotch acre, and the whole covered up. In this state it lay till the usual period of sowing in May, when the whole was found to be in a highly pulverised state, equal to the finest garden mould—only covered with a large crop of surface weeds, an article abundantly prolific on this farm. To remove the surface-weeds the drills were lightly harrowed, and a potato-grubber passed between them, and any soil that had thus been brought down was laid up by a double-moulded plough, and the seeds. Purple top Swedes, sown on the 11th of May. The result of this experiment seems clearly to indicate that in a similar way soils of even the most stubborn nature may be prepared for Turnips, and

though it is not pretended that there is anything novel or particular in this mode of tillage, yet as it is not generally practised, it may be of use to keep it before the public. When the crop began to be lifted, a friend suggested the idea of having a part of the field measured and the crop weighed, which was accordingly carefully done, and though this season has generally been considered not the most favourable to the growth of Turnips, yet the result in this case was found to be at the rate of 28 tons 18 cwt. of cleared bulbs per Scotch acre. The same variety of Turnips was grown on another field of this farm, but here the soil was a light loam on a gravelly bottom. This field received an equal quantity of the same sort of manure laid on the stubble, and ploughed in betwixt the 10th and 17th October last, and cross-ploughed and prepared for seed in the last week of April and 1st of May, and sown on the 22d May. A similar space of this field was measured and the crop carefully weighed, giving at the rate of 24 tons 5 cwt. of cleared bulbs per Scotch acre. If the additional produce be the result of the different period of tillage in the former case, and there is no reason to doubt that it is, this is another reason why the practice should be brought into public notice.—*Alexander Ross, Farm Overseer, N. Berwick Abbey.—Kelso Warder.*

Gluten in Grain.—The quantity of gluten in Wheat, Rye, and Barley, is very different; and they contain nitrogen in varying proportions. Even in samples of the same seed the quantity varies; and why? Evidently because one variety has been better fed with its own appropriate fertiliser, than another which has been reared on a soil less accurately adapted by artificial means for its growth. French Wheat contains 12 per cent. of gluten; Bavarian, 24 per cent. Sir H. Davey obtained 19 per cent. from winter, and 24 from summer Wheat; from Sicilian 21, from Barbary Wheat 19 per cent. Such great differences must be owing to some cause; and this we find in the different methods of cultivation. An increase of animal manure gives rise not only to an increase in the number of seeds, but also to a remarkable difference in the proportion of gluten which those seeds contain. Among manures of animal origin there is great diversity. Cow-dung contains but a small proportion of nitrogen. One hundred parts of Wheat, grown on a soil to which this material was applied, afforded only 11 parts of gluten, and 64 of starch; while the same quantity of Wheat, grown on a soil fertilised with human urine, yielded 35 per cent. of gluten, and, of course, a smaller proportion of less valuable ingredients.—*Smith's Productive Farming.*

Notices to Correspondents.

Our Correspondents will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

Agricultural Machines.—*Nemo.*—We shall, in the course of this year, publish a series of articles on this subject in the *Gazette*, which we shall endeavour to make *practically* useful to our readers.

Bone-dust.—*A. H.*—Apply from 2 to 3 qrs. per acre. Bone-dust acts more powerfully on light than on clayey soils.

Buckwheat.—*H.*—Light soil suits this plant; sow it after the rate of 1½ bushel per acre, broadcast, at any time between the beginning of May and Midsummer.

Books.—*J. S.*—Griesenthwaite's "Theory of Agriculture" is a good work on the general subject of Agricultural Chemistry. The article by the late Rev. W. L. Rham, on the "Analysis of Soils," in the 1st vol. of the English Agricultural Society's Journal will teach you how to execute a rough analysis. The "Elements of Chemical Analysis," by E. A. Parnell, Esq., is the most complete work on the subject we know, but it requires a practical knowledge of Chemistry before it can be made use of.

Clover Lea.—*Jack Spratt.*—Sow Italian Rye-grass in the blanks early in March, during wet weather, and rake or harrow it in.

Effect of Winds on Vegetation.—*J. Russell.*—There is no doubt that the shaking and stirring of plants by winds benefits them when it is not too violent, but the cases of fertility in upland districts which you may have noticed, cannot be attributed to this, as they are decidedly exceptions to the general rule. The lateness of the crops at the gateways of fields is owing to the trampling of the land there. If any of the facts on which you base the opinions you allude to have any useful bearing on Agriculture we shall be glad to publish them.

Feed for Young Cattle.—*A Subscriber.*—Your best plan will be to give them 4 lbs. of oil-cake a-piece daily, and Straw *ad lib.* The oil-cake will cost you 1*s.* 9*d.* a week.

Geological Map.—*A Notts Farmer* will find the Geological Map of England, by G. B. Greenough, Esq., sold at the Geological Society's rooms, Somerset House, to be the best published "on a large scale." Maps of particular districts are to be had, but there is no *series* of county geological maps published. This desideratum is being supplied by the maps of the Ordnance Geological survey now proceeding.

Grasses for Cover.—*H.*—Messrs. Lawson and Sons recommend for cover Aira cæspitosa, Arrhenatherum avenaceum, Brachypodium sylvaticum, and Bromus giganteus, with some others of less importance. To these we should add more of the coarse hedges, such as Carex pendula, acuta, paniculata, and lævigata. —*J. L.*

Horse-crushing Machines.—*J. T. Nicol, M.D.*—See article on Corne in this and next Numbers of the *Gazette*. We shall take up this subject in the course of our articles on Agricultural Mechanics.

Inorganic Constituents of Onion-tribe.—T. *Price.*—We have not been able to meet with an analysis of the Onion.

Mange.—*Trefoil.*—This is an extremely infectious disease, and consists essentially in the presence of an infinite number of minute insects, invisible to the naked eye, which pierce the skin, and thus produce the well-known irritation. Its cure is effected by totally destroying these insects, which can be done by the application of several drugs; but from the circumstance of the bodies of horses and cattle being covered with hair, and occupying so large an extent of surface, it often happens, that while the infection is removed from nine-tenths of the body, one-tenth may continue diseased, and re-infect the whole, or where a number are affected, those convalescent may again receive the complaint, either from those only partially cured, or from contact with the stalls or mangers against which the animals may have previously rubbed. All these liabilities must be guarded against in accomplishing a cure. The animal should be first well washed with soap and water, and when dry, the following application should be thoroughly rubbed in, either with the hand or a brush, over every part of the body. This should be repeated every alternate day two or three times, and then the animal should be again well washed, and examined, and if necessary, the process repeated. Amongst a very numerous class of prophylactics which the writer has employed with success, the old remedy, sulphur, stands first, and the following combination he considers the best:—Sulphur powdered, 1 lb.; white Hellebore, 1 oz.; oil of tar, ½ lb.; Linseed Oil, sufficient to make a semi-fluid mixture, or liniment. The mangers, racks, stalls, &c., should be washed from time to time with warm water, and afterwards with a solution of chloride of lime, or white ash.—*W. C. S.*

Manures.—*A Constant Reader.*—Cover up your minced horse-flesh, a most valuable manure, with plenty of fresh mould, and wait till it has rotted, and then mix it all up together before you apply it to the land. Your fresh-grubbed wood-land is surely full of vegetable matter already. Your best plan is to plant it to Potatoes in spring, and then sow Wheat in autumn. Ammoniacal liquor should not be applied so very long before the land is to be grubbed up. You had better wait till a week or a fortnight before planting the ground. The bones referred to in the Leader, No. 3, *Agricultural Gazette*, were, we believe, boiled bones.

Markets.—*W. R.*—The report of the wool market by Mr. Perrin does not refer to the London market exclusively, but to the general state of the British wool trade. Can you suggest one or two markets for feeding stock the report of which would be *generally* useful?

Nitrate of Soda.—*Omega.*—Scatter it in wet weather broadcast; that will do as well as dissolving it; but whichever way you do, you may apply from 1 cwt. to 2 cwt per acre.

Operation on the Snouts of Pigs.—*F.*—There are two tendons which, with their parent muscles, elevate the snout, and endow it with the power of rooting up the earth. These tendons may be divided about an inch-and-a-half from the nose. A portion of each should be excised, and the wound kept open a while by means of a little tow; a simple division of these would answer no end, as they would soon unite again: but by cutting out a portion, their power would, to a certain extent, be destroyed. The operation is, however, by no means customary in these parts, and I cannot speak from experience of its practical benefit, but am inclined to doubt its superiority to the old practice of ringing.—*W. C. S.*

Potatoes.—*Economist.*—Philipp's Purple will answer your purpose as well as any other. All Potatoes are the better of steaming. The Mangold Wurtzel Potato is very moist, and of bad quality, though it is a large bearer.

Rats.—*Nemo.*—Try smearing their holes, and the passages they frequent, with some arsenical ointment. They are very cleanly animals, and if they rub themselves against any of the greasy ointment, they will lick themselves clean.

Refuse Lime from Gas-works.—*Amicus.*—Make it into a compost with mud, earth, &c., in the proportion of one of the former to six of the latter, and turn frequently so as to expose it as much as possible to the air. Apply at the rate of 12 to 20 cart-loads an acre. The above figures are quite arbitrary; a smaller quantity of earth to mix it with might do equally well. Do not apply it close to the seed or growing-plant.

Salt.—*N. H. Grillon* wishes to be informed whence Mr. Mackenzie has quoted the words printed in a late No., in inverted commas, "salt of the earth."

Sainfoin.—*G. D. V.*—Sainfoin may be sown with a crop, as Clover or Grass. Sow four bushels of it per acre, in the end of March. Barley is the best crop to sow it with. It likes a calcareous rocky soil, and probably would not flourish on a deep sandy loam.

Steeping Seeds.—*T. Price.*—See Leader, No. 4, *Agricultural Gazette*.

Sulphuric Acid and Bones.—*Anonymous.*—Superphosphate of lime is prepared by submitting dry bones to the action of three-fourths their weight of sulphuric acid, which has been previously diluted with its weight of water. It is obtained in the form of a solution, and must be thrown upon dry earth, or sawdust, or something of the kind, in order to carry it to the field. Sulphuric acid is sold at from 1½d. to 2d. per lb. by wholesale manufacturing chemists. We have written to Mr. Campbell for an answer to your question.

Task-work.—*A Subscriber.*—The dung was measured before turning. 5*s.* or 6*s.* a week, with some cider, a quart or so per diem is the average wage of the labourer in this neighbourhood; but this is of little importance in estimating the proper payment to be made, as may be illustrated by the answer which the story tells us a labourer once made to a farmer, who asked the wages he was willing to be hired at: "Why, master, I've got a shilling stroke, an eighteenpenny stroke, and a two shilling stroke; and you may have just which you've a mind to."

*** As usual, many communications have been received too late for answering this week.

Markets.

SMITHFIELD, Monday, Jan. 29.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3*s* 10 to 4*s* 2	Best Downs & Half-breds	4*s* 0 to 4*s* 4
Best Short Horns	3 6 3 10	Best Long-wools	3 10 4 2
Second quality Beasts	3 2 3 6	Ewes and second quality	3 4 3 8
Calves	4 6 5 4	Pigs	3 4 4 4

Numbers.—Beasts, 2744; Sheep, 26,170; Calves, 83; Pigs, 270.

The supply continuing moderate, there is a brisk trade to-day, but very little alteration in prices. The best Scots, Herefords, &c. were readily sold at fully last week's prices, but the Short-horns were heavy on hand, barely maintaining our last quotations. In Sheep, the Long-wools were in demand at a slight advance, owing to the continued improvement in coarse wools; other qualities remain about the same. Veal is still dear. Pork is very heavy trade.

FRIDAY, Feb. 2.

Our supply to-day is rather larger than last Friday, and the roughness of the weather has caused a slack attendance of buyers. Beef is a little lower, say 2*d.* per 8 lbs. Mutton is about the same as Monday. Veal is quite as dear; indeed, in some instances the very best have realised 5*s.* 6*d.* per 8 lbs. Pork is a little more in demand.

Numbers.—Beasts, 658; Sheep, 2280; Calves, 134; Pigs, 290.

41, West Smithfield

POTATOES.—Southwark Waterside, Jan. 29.

Having had during the past week a continuance of fine weather, which has brought the Turnip-tops into the Green Market earlier and more abundant than usual, and consequently arrested the improvement in the demand for Potatoes, though holders of Scotch Reds have increased their pretensions; yet where it was necessary to clear vessels owing on demurrage, no advance whatever could be obtained on last week's price. We have quoted 70*s.* for Perth and Devonshire Reds, as that price has been generally asked, but can only be regarded as nominal.

York Reds	0*s* to 80*s*	Kent and Essex Whites	50*s* 55*s*
Perth	65 70	— — Kidneys	— 65
Early Devons	65 70	Wisbeach Kidneys	— 65
Cornwall	65 70	— White and Blue	50 55
Jersey and Guernsey Blues	60 —	Prince Regents	55 65

The supply during the past week has been limited; but these, with former arrivals, have been fully sufficient for the present demand.

SEEDS, Friday, Feb. 2.

Canary	per qr 48*s* to 52*s*	Linseed Cakes, Foreign, p. ton	6*l* to 7*l* 10*s*

Kinnersley and Lee.

WOOL.—British, Friday, Feb. 2.

We cannot report any alteration in our English Wool Market during the past week. Things continue firm. The first of the series of Colonial Wool Sales was held last evening at the Hall of Commerce; the attendance of buyers was large.

Prices Current.

	per lb.				per lb.	
Long-wooled Wethers	1*s* 0½	to	1*s* 1½	Southdown Hoggetts	1*s* 1*d*	to 1*s* 3½
&c. Hoggetts	1 1		1 3	Kent Fleeces	1 1	1 3½
Southdown Fleeces	1 0		1 1			

James Perrin, Wool Broker.

MARK LANE, Friday, February 2.—The arrivals of Corn since Monday have been small, which is in some measure attributable to the stormy state of the weather; the few samples of English Wheat fresh up have been disposed of at fully Monday's prices. The inquiry for free Foreign Wheat is limited, but in some instances the finest qualities realise a trifling advance. We have not heard of any transactions in bonded to-day.—Barley meets a steady sale at our quotations.—In Beans and Peas we observe no alteration.—Oats are held firmly by the Factors at late prices, with which the buyers are unwilling to comply.

Kinnersley and Lee.

COVENT GARDEN, Feb. 2.—Notwithstanding the great change that has taken place in the weather, the market has been tolerably well supplied during the week, and little alteration has taken place in the Prices of most articles; but trade is not brisk. Pine Apples continue scarce, and have advanced a little in price since our last report; they are rather small, and consist principally of Queens. No hothouse Grapes are now to be found in the market, but Portugals continue sufficient for the demand. The supply of good dessert Pears is rather on the decrease; good specimens of Beurré Rance and Easter Beurré have, however, been brought to the market, and are offered at nearly the same prices as last week. The prices of Apples are also nearly the same as those quoted in our last report. Tangerine Oranges continue to be brought to the market. Lemons are plentiful, and Filberts are sufficient for the demand. Among Vegetables, Cabbages are good and plentiful, Brussels Sprouts and Greens are also abundant; but Broccoli still continues scarce. The supply of Lettuces and Endive is pretty good. Scalade and Rhubarb are sufficient for the demand; Shallots and Onions are good and plentiful. Asparagus is rather scarce. Celery is sufficient to meet the demand, but is rather inferior in quality. Among Cut Flowers we noticed Erica gracilis and hyemalis, Cypripedium insigne, Euphorbia splendens, Lachenalia tricolor, Combretum purpureum, Bignonia venusta, Cinerarias, Acacias, Primulas, Tulips, Hyacinths, and Fuchsias, Pelargoniums and Roses.

FRUITS.

Pine Apple, per lb. 4*s* to 8*s*	Almonds, per peck, 8*s*
Grapes, Portugal, per lb. 1*s* to 2*s* 6*d*	Sweet Almonds, per lb., 2*s* 6*d* to 3*s*
Apples, dessert, p. bush. 4*s* to 10*s*	Nuts, Spanish, per bushel, 16*s*
— Kitchen, p. bus. 3*s* to 6*s*	— Brazil, 16*s*
Pears, per half-sieve, 4*s* to 12*s*	— Hazel, 2*s* to 4*s*
Oranges, per dozen, 10*d* to 2*s*	— Barcelona, 20*s* to 28*s*
— per 100, 14*s*	— Cob, per 100 lbs., 80*s* to 100*s*
Lemons, per doz. 2*d* to 3*s*	Chesnuts, per peck, 3*s* to 6*s*
— per 100, 5*s* to 14*s*	Walnuts, per bushel, shelled, 16*s* to 20*s*
Red Capsicums, 4*s* to 8*s*	Filberts, English, p 100 lbs., 30*s* to 35*s*,

VEGETABLES.

Rhubarb, per bundle, 6*d* to 1*s* 6*d*	Garlic, per lb. 4*d* to 6*d*
Broccoli, per bundle, 1*s* 6*d* to 3*s*	Onions, Spring 1*s* 6*d* to 3*s* p. bush.
Brussels Sprouts, per hf.-sv., 1*s* to 2*s*	— Large, per bushel, 3*s* to 6*s*
Cabbages, per doz., 6*d* to 1*s*	— Spanish, per doz., 1*s* 6*d* to 3*s*
Red Cabbages, per doz. 3*s* to 3*s*	— pickling, p. hf.-sv., 3*s* 6*d* to 4*s* 6*d*
Sorrel, 3*d* to 1*s* per half-sieve	Shallots, per lb., 6*d* to 9*d*
Asparagus, per 100, 2*s* 6*d* to 11*s*	Chilis, per 100, 1*s* to 2*s*
Sea-kale, per punnet, 6*d* to 9*s*	Lettuce, Cabb., p. score, 6*d* to 1*s*
French Beans, 3*s* to 4*s* per 100	— Cos, per score, 6*d* to 1*s*
Autumn Potatoes, 3*d* to 6*d* per lb.	Celery, per bun., 6*d* to 2*s*
Savoys, per doz. 6*d* to 1*s*	Mushrooms, per pottle, 6*d* to 1*s* 6*d*
Greens, per doz. 2*s* to 3*s* 6*d*	Small Salads, per punnet, 3*d* to 6*d*
Potatoes, per ton, 80*s* to 110*s*	Watercress, per doz. bun. 2*d* to 6*d*
— per cwt., 2*s* 6*d* to 3*s*	Parsley, per doz. bunches, 3*s* to 4*s*
— per bushel, 1*s* 6*d* to 2*s* 6*d*	Tarragon, Green, per bun. 6*d* to 9*d*
— Kidney, p. bush., 2*s* to 2*s* 6*d*	Endive, per score, 1*d* to 2*s*
Turnips, per doz. bunches, 1*s* 6*d* to 3*s* 6*d*	Green Mint, 4*d* to 6*d* per bunch
Horse Radish, per bundle, 1*s* to 1*s* 6*s*	Marjoram, green, p. doz. bun. 1*s* 6*d* to 2*s*
Radish, spring, p. doz. bunch, 1*s* to 2*s*	Chervil, per punnet, 6*d* to 9*d*
Carrots, p. doz. bun., 2*s* 6*d* to 3*s*	Salsafy, per bundle, 1*s* to 1*s* 6*d*
Spinach, per sieve, 1*s* 6*d* to 2*s*	Scorzonera, per bundle, 1*s* 6*d*
Leeks, per doz. bun., 9*d* to 1*s*	

HOPS, Friday, Feb. 2.

There is no alteration in the Hop Market since last week. Prices are fully maintained, and the supply very limited.

Mid & East Kent Pocks.	8*l* 0*s* to 10*l* 10*s*	Sussex Pockets	6*l* 0*s* to 6*l* 6*s*
Choice ditto	11 0	Choice ditto	6 15
Weald of Kent Pocks	6 0 6 15	Farnham	9 9 10 10

Martin's Early Globe Potatoes		2s.	,,

A choice selection of Pot Roots of all the best varieties of Dahlias in cultivation, from 1s. to 2s. 6d. each.
Lilium lancifolium album, 4s. each.
Double Tiger Tuberoses, 4s. per doz.
Tigridia pavonia, 3s. per doz.
Fine Double Anemones, 10s. per lb.
Single Do. 4s. per lb.
Splendid mixed Ranunculus, 3s. to 8s. per 100.
Myatt's Victoria Rhubarbs (true from the raiser), 1s. 3d. each.
Marshall's Early Scarlet Rhubarbs, 9d. each.
Lancashire Gooseberries, in fine variety, 8s. per doz.
Grape Currants, 6s. per doz.
Mixed Grasses for Lawns and Pastures, of the very finest quality. Selections of Seeds carefully assorted and packed for all climates.
Standard and Dwarf Roses, in fine variety.
Metallic Wire and Labels, Garden Tools, Knives, &c. &c.
Agents for the Sale of Humphreys's Compound.

HURST and M'MULLEN beg to thank their Friends for the kind and encouraging patronage they have received, and to assure them that all commands shall have careful and prompt attention. —Wholesale and Retail Seed Establishment, 6, Leadenhall-street; Warehouse, 19, Vine-street, Minories.

JAMES DICKSON & SONS, NURSERY SEEDSMEN and FLORISTS, in returning their sincere thanks for the liberal patronage they have hitherto enjoyed from the Nobility, Gentry, and Public at large, both in this Country, England, and Ireland, beg respectfully to intimate that they have received their Full Supply of SEEDS, in fine condition, for SPRING SOWING, of first-rate quality.

From the arrangements they have recently made with some of the first Growers, their Customers may depend on receiving Fresh Seeds of all descriptions, carefully selected for J. D. & S.'s Sales.

J. D. & Sons beg to call the attention of their Friends to their Stock of EVERGREENS, FRUIT and FOREST TREES, in their Nurseries of Inverleith and Broughton Park, which will be found equal in quality and extent to any in Scotland.

J. D. & Sons beg further respectfully to intimate that they have considerably extended the Floral Branch of their Business; and they assure their numerous Customers and the Public at large that no pains or expense will be spared by which the efficiency of every department of the concern shall be secured, so as to ensure a first-rate article at the lowest figure.

Catalogues of every article connected with their trade have just been published, and can be forwarded, per post, on the receipt of postage stamps to the amount of sixpence.

N.B.—Noblemen and Gentlemen provided with experienced GARDENERS, LAND STEWARDS, and WOOD FOREMEN, whose character and abilities may be depended on.—23, SOUTH HANOVER-STREET, Edinburgh, January 31, 1844.

SEED TRADE—NO MONOPOLY.

J. G. WAITE, WHOLESALE SEEDSMAN, 1 & 4, Eyre Street-hill, Hatton Garden, London, most respectfully solicits the attention of the Country Trade to his prices of SEEDS recently advertised in the *Chronicle*, and to remind them that everything is quoted very much below the *London Agreed List*. All articles sold at his Establishment are of superior Quality, and genuine Stock-lists to be had on application.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

RENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks which are ornamental in appearance can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

THE CONICAL HOT-WATER BOILERS, invented by J. ROGERS, Esq., may be obtained of any size from JOHN SHEWEN, Ironmonger, &c., Sevenoaks, Kent.

J. SHEWEN having had every opportunity afforded him by an extensive practice to bring this apparatus to perfection, begs to offer it as most efficient and economical: it may be seen at Messrs. Chandler & Sons' Nursery, Vauxhall; Messrs. Loddiges', Hackney; Messrs. Henderson's, Pine Apple-place; Messrs. Veitch and Son's, Exeter; Mr. Pontey's, Plymouth; the Royal Botanical Society's Gardens, Regent's Park; and at the Gardens of the Horticultural Society of London. Considerable improvements have been effected since last season; particulars of which are in course of preparation.

CHEAP FUEL FOR HOTHOUSES AND STOVES. —Coke, the same as used by the Horticultural Society, to be had in large quantities, at very reduced prices, at the Phœnix Gas Works, Bankside, or Greenwich.

CHARCOAL FOR SALE.—1000 bushels of Charcoal for sale, in quantities of 100 bushels and upwards. Apply to T. H. DARTON, near Hitchin, Herts.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement, may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melon-pits, &c. &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &c.

GUANO.—The Subscribers will bring in a cargo of this MANURE to Berwick-upon-Tweed, in all February and March, direct from Valparaiso.
Haddington, Jan. 22, 1844. BANKS & SON.
Note.—As this will be one of the very few cargoes from the Pacific, whose charterparties will admit of their discharging on this coast, BANKS and SON would recommend intending purchasers to apply for what they may require as early as possible.

POTTER'S GUANO.—Sir Robert Peel, the Earl of Zetland, and others, have used POTTER'S MANURE with the greatest success on almost every kind of crop and soil. Testimonials may be obtained by application, per post, at the Works, 28, Upper Fore-street, Lambeth, or of any of Mr. POTTER'S agents.—See also the Advertisement in this Paper of the 6th Jan., containing some of the Testimonials referred to.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.
Lists of Prices, with synopsis of mode of use, on applications to MARK FOTHERGILL, 46, Upper Thames-street, London.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7s. per cwt.

Phosphate of Potash		18s. per cwt.
,, Soda		12s. ,,
,, Magnesia		9s. ,,
,, Ammonia		1s. per lb.

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine as imported,—Apply to COPESWORTH, POWELL, and PAYNE, London; EDWARDS, DANSON, and Co., Liverpool; or WILLIAM J. MYERS and Co., Liverpool, the Importers.

GENUINE PERUVIAN & BOLIVIAN GUANO ON SALE, BY THE IMPORTERS, ANTONY GIBBS AND SONS, LONDON; GIBBS, BRIGHT, AND CO., LIVERPOOL AND BRISTOL. 47, Lime-st., Jan. 31, 1844.

GUANO ON SALE BY THE IMPORTERS, JOHN BOYD & Co., Wellington Chambers, London Bridge, Borough.

LIQUID MANURE.

PUMPS of a Superior Construction, fixed and portable, for Liquid Manure. Garden Pumps, Hydraulic ditto, and Pumps for deep wells. Also Pumps for Ships, Barges, Tanners, Soap Boilers, Brewers, &c. Well-Digging and Boring executed. BENJAMIN FOWLER (late George Turner), 63, Dorset-street, Fleet-street.

TO AGRICULTURISTS.—IMPORTANT DISCOVERY.
"Quid faciat lætas segetes"—VIRGIL.

THE CORN-PRODUCING LIQUIDS.—"One of the most extraordinary exhibitions in the yard (at the late Agricultural Show, Dundee), was that presented by Mr. JAMES CAMPBELL, of the Dundee public seminaries. It consisted of magnificent plants of Oats and Barley, grown from seed which had undergone a certain chemical preparation, and without the aid of any manure whatever.

"Such a mode of culture is at variance with all practical experience; but Mr CAMPBELL declares that his prepared seeds, which have produced these strong, healthy plants, were sown by him on land which, to his certain knowledge, had had no manure of any kind for eleven years; and he declared himself quite ready to verify his statement by experiment, and said he was willing, at any time, to impregnate with his chemical preparations the seed which any member of the Society should send to him for that purpose, so as to enable gentlemen to satisfy themselves fully as to the efficacy of this wonderful mode of culture."—*Journal of Agriculture, October*, 1843.

In this discovery is actually realised that boast of science, which some years ago prophetically asserted, that the time would soon come when one might carry in his pocket matter sufficient to manure an acre of land.

After impregnation with these liquids, the seed possesses within itself elements which not only afford additional nourishment to the grain during the progress of germination, but communicate to the expanding vessels of the plant an aptitude to absorb food, both from the soil and the atmosphere.

Of one specimen of Oats exhibited, the average produce of 32 seeds was 1600 grains from each, or a total of 52,800 grains, weighing 46 lbs. per bushel.

The produce of Barley was an average of upwards of 500 grains from each seed sown; and of Wheat sown on 5th July, and taken up on 8th August, to be exhibited, the result was, that while the unprepared seeds gave plants with two, three, and four stems only, the impregnated grain yielded plants with nine, ten, and eleven stems.

The material for these liquids, at the following prices, may be had of the following Agents.

Wheat	material for one gallon	2s.	6d.
Barley	do.	2	9
Oats and Grasses	do.	1	6
Beans and Peas	do.	2	6
Turnip and Rape-seed	do.	2	6

Agents:—Messrs. GEORGE GIBBS & Co., Down-street, Piccadilly, London; JAMES HADEN, Ironmonger, Warminster, Wilts; JOHN CAMPBELL, 5, Mersey-street, Liverpool; E. R. CROUCH, Newcastle-on-Tyne; SAMUEL WALDIE, Carlisle; W. W. FYFE *Agriculturist* Office, Berwick; Messrs. P. LAWSON & SON, Edinburgh; DRYSDALE & Co., Glasgow; DRUMMOND & SON, Stirling; and DICKSON & TURNBULL, Perth.

One third, or even one-half less grain, is required for seed than is commonly used; and twelve gallons will impregnate eight bushels of grain; for the operation may be repeated in the residual liquid with additional measures of grain, as not more than one-tenth is absorbed in each operation.

Particular printed instructions for using the liquids will accompany invoices. No order under 20 gallons will be supplied.
1, Dudhope-street, Dundee.

MANURE FOR GRASS, &c.—POTTER'S GUANO.
Testimonial of Lord Zetland, Dec. 2, 1842.

POTTER'S GUANO, 2 cwt. per acre, yielded of *Hay*	2 tons	8	cwt.
Peruvian Guano, 2 cwt. per acre, yielded of *Hay*	1 ,,	16	,,
Difference in favour of Potter's Guano		10	cwt.

BEAUTIFUL FLOWERS. — POTTER'S CONCENTRATED LIQUID GUANO, in quart bottles, 1s. 9d. each, at the principal Chemists and Seedsmen in town and country.

"I used POTTER'S GUANO on my Pansies; they were *much larger* than I ever had them before, and remained in full blow longer than I ever recollect. JOHN RITSON, Sunderland."

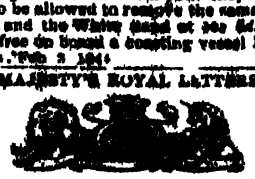
"POTTER'S GUANO will convert your desert into a paradise."—Professor LINDLEY, in *Gardeners' Chronicle*, 1843, p. 560.

Works, 28, Upper Fore-street, Lambeth.

For further testimonials see this Paper of the 6th Jan., 1844.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.
EDWARD PURKIS, Secretary, 40, New Bridge Street.

GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.



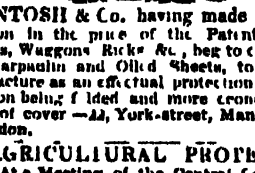
Noblemen, Gentlemen, and Gardeners will, by using this composition have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

Sold in Bottles, with directions for use, pints, 2s. 6d., quarts, 4s. 6d. each. One pint is sufficient to coat four Frames twice over, each Frame to be 8ft. by 3 ft. 3 in., or thereabouts. Prepared by GEORGE WHITNEY, Chemist, Shrewsbury. Seedsmen, Florists, and Merchants supplied by Mr. W. BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. BUTLER and MUCKLEY, Covent Garden, where a sample of prepared calico may be seen; Mr. WATKINSON, Market-place, Manchester; PAGE and SON, Southampton; T. and C. WHALLEY, Nurserymen, Liverpool.
Agents wanted for London and the country.

HEATH-SOIL.—Numerous gentlemen, visitors, at Bournemouth, having applied to R. Waters & Colefor supplies of the fine Heath Peat Soil which abounds in that locality, they beg to inform them that they have now made arrangements to be allowed to remove the same, and can consequently offer it and the Whitey Sand at 20s 6d. per cargo load-head, delivered free on board a coasting vessel here

Poole Nursery, Feb 3 1844

BY HER MAJESTY'S ROYAL LETTERS PATENT.



PATENT ASPHALTE ROOFING

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally as a Roofing and Covering to sides of Farm Buildings its advantages are—Lightness, Durability, and Economy Being a bad conductor of heat, it has been proved an efficient "Protective Material" to Plants, and is now in use at the "Royal Horticultural Society's Gardens, Chiswick." It can be had of any length, 32 inches wide at 1d. per foot, super. A discount to the trade

SUPERIOR SUBSTITUTE FOR TARPAULIN, &c

C. MACINTOSH & Co. having made a considerable reduction in the price of the Patent India Rubber Covers for Carts, Waggons Ricks &c, beg to call the attention of Users of Tarpaulin and Oiled Sheets, to the superiority of their manufacture as an effectual protection against wet not liable to crack on being folded and more economical than any other Waterproof cover —44, York-street, Manchester, and 46 Cheapside, London.

ESSEX AGRICULTURAL PROTECTION SOCIETY.—At a Meeting of the Central Committee at the Saracen's Head, Chelmsford, on the 26th January, Mr Robert Baker, Chairman, the following Resolutions were agreed to —

That it is the opinion of this Committee that the great demonstration of feeling on behalf of protection to Agriculture originating in the Chelmsford Meeting, and since followed up by most of the counties of England holds forth a reasonable prospect that the great object in view may be accomplished without (at all events in the present stage recommending the preparation of petitions to Parliament

That this Committee at present entertain no intention of employing lecturers throughout the county as advocates on its behalf. Chelmsford, Jan 26 1844 H T Biddell Sec

SPALDING ASSOCIATION for the PROTECTION of AGRICULTURE.—At a Meeting of the Members of the above Society, and of other parties interested in the Protection of Agriculture, held, pursuant to advertisement, at the Town Hall, Spalding, on Jan 24, Robert Everard Esq, in the Chair, the following Resolutions were unanimously adopted —

1. Resolved, That it is the bounden duty of all parties in any way dependent upon the prosperity of British Agriculture, to oppose to the utmost the efforts of the Anti Corn-Law League, engaged as the members of that League are in an unconstitutional conspiracy, adverse alike to the Agricultural interest generally, and to the stability of the most valued institutions of the country

2 Resolved, That the protection afforded by the present Corn Law is barely sufficient to keep up the progressive improvements in Agriculture, and that if the efforts for extended improvement cease, as must be the case if protection were withdrawn, the increasing population of this country would be dependent for support on the production of foreign countries.

3. Resolved, That the evils of a free trade in Corn are generally considered only through the medium of the low prices which would result from the withdrawal of protection, but this meeting considers that free trade would induce such a superabundant importation of foreign corn that the home grown product would not at all times find a market at any price, and that the having to wait for a market for British grown Corn would more than any other cause, occasion the poorer tracts of land to be altogether thrown out of cultivation, and the labouring classes employed thereon to lose their only means of support

4. Resolved therefore, That this Meeting do pledge themselves not only not to give their support to any Government or party which shall, either directly or indirectly, attempt to deprive the Agricultural classes of any portion of the protection afforded by the present Corn law, but that they will by every constitutional means oppose any proposed diminution of such protection

5 Resolved, That a Petition to Parliament against any further alteration in the Corn laws be prepared, and that copies thereof be sent to some influential person in each of the neighbouring parishes for the signatures of the landed proprietors, occupiers labourers, and other parties dependant upon Agriculture, and that such petitions be transmitted to the Members for this division for presentation in the House of Common

6 Resolved also, That it is highly expedient that this Association be extended for the general protection of British Agriculture, and to co operate with any societies of a similar character, or with any central or general association in this county in opposing the exertions of the Anti Corn Law League, and that a subscription be opened to enable such Association to act as the exigency of circumstances may require

Resolved also, That the above Resolutions be advertised

Robert Everard, Chairman

Mr Everard having vacated the chair, it was Resolved that thanks be given to him for his able conduct of the proceedings

CURTIS'S BOTANICAL MAGAZINE.—Just published, price 3s 6d coloured, No. 398 of the New Series of this interesting and scientific work, edited by Sir William Jackson Hooker It contains beautifully coloured figures of Cereus Eatonus—Dioscea Polybulbon—Ipomæa crassipes—Erica Shannoniana—Tetranema Mexicanum—Scaphyglottis violacea. The above work has been published monthly, without any intermission, for the last fifty eight years, and stands unrivalled by any other botanical publication in beauty and extent The whole or any part of the work from its commencement may be had of Mr. Samuel Curtis, at the Botanical Magazine Warehouse, Glanswood, near Braintree, Essex.

THE IRISH FARMERS' GAZETTE and HORTICULTURAL JOURNAL Edited by Edmund Murphy, A B, J C D, Landscape Gardener and Improver of Estates, &c.

This Paper was commenced in May, 1843, and having been adapted to the circumstances of Irish Farming now in a transition state from the worst to an excellent system—not only points out the best practice, but, giving plain instructions how every operation should be performed, is now recognised as the ORGAN of AGRICULTURAL IMPROVEMENT in IRELAND, where the advantages which have already resulted from it are universally recognised The result of practices recommended, and of experiments on all subjects connected with the improvement of land, and the increase of its product, are freely communicated to the Editor and recorded. Selections of the most practically useful articles are made from the various works on farming with which the press now teems, and utterly eschewing politics—so long the bane of the Irish Farmer—and devoting its columns exclusively to Agricultural and Horticultural improvement.

THE FARMERS' GAZETTE has the distinguished honor to be stamped with the approbation of those eminent individuals, Wm Blacker Esq, James Smith, Esq, of Deanston, and the late Mr Loudon, and is received with such confidence that the practice of having its contents read at stated periods to assembled farmers is becoming general. The circulation of the IRISH FARMERS GAZETTE has of late been extending even in England and Scotland, where, up to this period, no effort has been made to bring it under notice, but where the principles of good husbandry being everywhere the same, it is calculated to be equally useful as it has been found to be in Ireland. The most practically useful essays on Farming are, from time to time, struck off for distribution in the shape of TRACTS FOR FARMERS, and have been very extensively circulated, viz — On the Dairy; A Catechism of Thorough Draining and Subsoiling; The Culture of Flax, Management of Manure, and Green-Cropping and House Feeding, are nearly ready Also, on the 1st Jan. was published, the "Irish Farmers, Gardeners, and Foresters' Almanac."

THE IRISH FARMERS' GAZETTE is published every Friday, at 32, Bachelor's Walk, Dublin, and goes free by post. Annual subscription 16s, half yearly, 8s, payable in advance, and orders directed to the publisher are immediately attended to

Each volume complete in itself

THE LATE Mr. LOUDON.—A Public Meeting of the Friends of the late Mr. Loudon will be held in the large room of the Horticultural Society's Establishment, Regent street, London, on Saturday, Feb. 17, at two o'clock precisely, to consider the best means of extricating his Widow and Daughter from the difficulties into which they are placed by Mr. Loudon's sudden death.

It is hoped that noblemen and gentlemen who patronise Horticulture, and also all Gardeners and Nurserymen who are within a reasonable distance, will attend

RESIDENCE, WANTED to RENT, placed in a park or parklike grounds. Must contain good entertaining rooms, five or six best bedchambers, with all suitable offices for not an extensive establishment, and if with a farm of 20 acres, would be desirable Would be taken on lease, and the occupant prove an unusually advantageous tenant. Full particulars and terms to be addressed to Messrs Hendee, Land Agents, 10, New Bond-street, opposite the Clarendon

E. P. FRANCIS, Nurseryman, Hertford, begs leave to recommend to the Nobility, Gentry, and the Trade in general, Snow's superb white winter BROCCOLI, in 2s. packets, containing half an ounce, which was advertised last season, and will be found to give general satisfaction this winter and the ensuing spring. Also Snow's Hybrid Prolific Green-flesh MELON, of most excellent rich sweet flavour, warranted to produce two and three crops in a season, from the same plants, has taken six first prizes at the North Herts and South Beds Horticultural Exhibitions, weight from 2 to 3 lbs, sold in packets, 2s each Also, Snow's Superb Walcheren CAULIFLOWER, which is found to be late and hardy, never runs, and produces beautiful large compact white heads, and is very dwarf. Sold in packets, 2s each, containing half an ounce.

E. P. F. begs also to recommend a very superior kind of Grange's White BROCCOLI, which produces large compact heads in the months of January, February, and March Sold in packets, 2s., containing half an ounce. The above, making four packets, if ordered together, may be had for 10s, at the Hertford Nurseries, or of Messrs Noble, Seedsmen, 153, Fleet-street, Messrs J. Warren & Son, London Bridge, and Mr. Flanagan, opposite the Mansion House, London

KENSINGTON NURSERIES.

RICHARD FORREST and Co. beg leave respectfully to direct attention to their GENERAL NURSERY STOCK, which was never finer than this season, especially the extensive and correctly named Collection of FRUIT-TREES — See Advertisement for Nov. and Dec 1843, of this Journal.

In consequence of the Lease of one of their Nurseries expiring, and being required for other purposes, R. F & Co. deem it necessary to assure their Customers everywhere that it will not occasion the slightest interruption in their business The Shop, Warehouses, &c. will remain undisturbed, and the ample provision which has been made in the adjoining Nurseries for this little change will insure the same supply, and attention to all the Customers, which they have uniformly experienced To those who have visited the Nurseries recently, these observations are perhaps unnecessary; but to those who have not had an opportunity of witnessing the improvement of their Stock, R F & Co consider this slight notice necessary to counteract any prejudice that might be raised in the minds of their numerous friends throughout these kingdoms and elsewhere.

NEW SEEDLING FUCHSIA "SIDMOUTHII" will be ready to send out in May next; price 10s 6d each, carriage free.—This magnificent variety was raised last year by Mr. Bartlett, Nurseryman, Sidmouth It may be considered the finest hybrid extant. The flowers are large and colour brilliant, is a strong grower and prolific bloomer, with fine foliage. A specimen flower was sent to the Editor of the *Gardeners' Chronicle* last October, who spoke so high in its praise that anything further is superfluous, beyond its character as above Visitors to Sidmouth will be gratified by viewing Mr. B.'s Collection of this lovely and graceful flower; having a mode of treatment peculiarly his own.

†,* To secure fine plants early orders are desirable.

SEEDS AND DAHLIAS.

LOUIS VAN HOUTTE, Gendt, Nurseryman and Gardener to the King of Belgium, begs to inform the Trade that his Price-current, 1844, 1s, 1t, and 1u, are sent out, containing the SEEDS and the DAHLIAS, and may be obtained by application to Mr. Geo. Rehan, Crutched Friars, London (if by letter post-paid).

FASTOLFF RASPBERRY.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, THE MOST NOBLE THE MARQUIS OF ALBA, THE EARL OF HARRINGTON THE EARL OF LIVERPOOL THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD BONDES, &c &c; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL and Co. have much pleasure in announcing they are now supplying fine Canes of the above highly valuable and much esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour

Those to whom Y and Co sent it last season have expressed their high admiration of its superiority over all other varieties, and has been awarded several prizes at various Horticultural exhibitions during the season As a proof they have not exaggerated its excellent qualities, fruit was submitted to Dr Lindley, (see *Gardeners' Chronicle* of the 22d July last, page 502), whose opinion of it is as follows —

"Fastolff Raspberry.—We have received from Messrs Youell, of Great Yarmouth, fruit of the Fastolff Raspberry, and we find it merits all that has been stated in favour of its excellence The fruit that we have received is very large, obtusely conical, and of rich flavour, far exceeding in this respect some other new and large varieties The plants bear abundantly and in long succession"

They also exhibited it on the 1st of August, 1843, before the London Horticultural Society, 21, Regent street, to which a prize was awarded It would therefore be unnecessary for Youell and Co to recommend it more fully, or with greater confidence, to the notice of the public, merely observing, that it continues in high perfection throughout the autumnal months, and has maintained its superiority in the most unfavourable soils and situations, and requires no other than the ordinary treatment of the old varieties

Fine Canes are ready for delivery, and can be sent with safety to any part of the United Kingdom (on the receipt of a Post office order), upon the following terms —

	£	s	d.
Packages containing 100 Canes	2	5s	0d.

London, February, 1844.

NEW DAHLIA, "SYRED'S HERO OF MAIDA" Colour, bright orange; well cupped, and very constant, strong robust habit, adapted for a back-row flower; and where colour is predominant in class showing it is superior to any orange yet out. Having been raised by an Amateur it was only exhibited for competition at Hammersmith, where it obtained the first Seedling prize, and at Stockwell Seedling Show, where it also obtained a prize.

Daniel Syred, Nurseryman, Bloomfield road, Maida-hill, Paddington, having purchased the stock of the above fine Dahlia, he has a few ground-roots left to spare, at 2l. each, and strong pot roots at 1l. 10s. each. Plants 1st May, 10s. 6d. each. The usual discount to the Trade. No objection to exchange roots or plants for any approved variety.—London, Feb. 1, 1844.

GENUINE BEECHWOOD MELON SEED.

R. GLENDINNING respectfully begs to inform the Cultivators of the MELON that he has had presented to him by Sir John S Sebright, Bart, Seeds of the *true* variety of his delicious MELON; for besides being one of the very best sorts known, it is of easy cultivation and a good bearer. This opportunity will enable gentlemen to procure it *quite genuine*, which is rarely the case, as the following note will testify —

"Beechwood, Feb 5, 1844.

"Sir,—I send you a small parcel of the Beechwood Melon Seed None that I have seen exhibited under that name, nor any that I have seen grown from Seed that has been bought, are of the true sort but have obviously been intermixed with other varieties I have grown no other for many years

"Your obedient servant,

"To Mr Glendinning "J. S. Sebright."

R G has also a few Seeds of the true SION FREE BEARING CUCUMBER, a splendid variety which has been nearly lost.

Packets of the above sent by post free.

Beechwood Melon, per packet . . . 3s.
Sion Free bearing Cucumber, per packet . 1s.

R G's Kitchen garden and Flower Seeds have been selected with great care, and embrace all the new and good kinds.

Chiswick Nurseries, near London, Feb 6, 1844

A SUCCESSFUL METHOD OF GROWING LISIANTHUS RUSSELLIANUS.

J CUTHILL has printed the whole account of his treatment of the above Plant It is said by Dr Lindley in the *Gardeners' Chronicle*, that he (J. Cuthill) is the most successful grower of it round London From its noble and splendid appearance, it must become as generally grown as any other tribe of plants. His large Plant this year had 600 blossoms on it, and gained the Large Silver Medal at the Royal South London Exhibition; and at the same show, eight more Plants, with nearly 2,000 blossoms, gained an Extra Prize. The Printed Directions and a Packet of Seed will be sent out at the moderate price of 2s 6d, also plants of the above, from 2s. to 4s each; they can be sent in little bulk until the end of this month, when they will begin to grow.

Cuthill's Celebrated Early Melon.—J C assures those Gardeners who have not grown it, that it is one of the most Early and Prolific ever known, his Early Black Spine Cucumber, the true Beechwood Melon, as exhibited before Dr. Lindley at Regent-street—the single packets 2s 6d. each, or 4s, for the four.

A Lad about 17 years' old wanted, board and lodging, with 2s per week, will be given, a small premium required.

Orders payable on Camberwell Post office. — Direct, Mr. Cuthill, Florist, Denmark hill, Camberwell.

, Fine Cucumber plants at any time

" " " large bulbs, each		0	10	6
" " punctatum, good bulbs, each		0	7	6
" " " large bulbs, each		1	1	0

Extensive may be had on application.—Jan., 1844.

GEO. CROFT, Forbury, Reading, begs to call particular attention to his Seedling Verbena "ADONIS"—a bright crimson, with large lemon-coloured eye. This is particularly recommended to Noblemen and Gentlemen's Gardeners for planting out in beds, as nothing can excel in beauty a bed of this splendid Flower. Plants in April, 2*s.* 6*d.*

Likewise to his Seedling Fuchsia "UNIQUE"—tube and sepals smooth; sepals expand well; corolla, rosy purple the plant is of beautiful habit and if the Public can judge, then this is one of the loveliest Fuchsias sent out. Plants in April 7*s.* 6*d.*

SHILLING'S EARLY GROTTO PEA.

J. AND S. SHILLING have succeeded in raising the above PEA, the Early Frame Pea, impregnated with the Scotch or Oyster Marrow, which they, with confidence, recommend to the Public generally, being quite as early, and nearly double the size of any other Pea in cultivation. Quite hardy, will stand the winter well, and a good bearer; the pod large and long. They would particularly recommend it to the attention of Market Gardeners. Price 2*s.* per quart, 10*s.* per gallon, 17*s.* 6*d.* per peck; 30*s.* per half-bushel, 2*l.* 10*s.* per bushel. Agents.—Messrs. PERRY and CHARD, 119, Lower Thames-street, London, Messrs. W. and J. NOBLE, 183, Fleet street; Mr. KERNAN, 4, Great Russell-street, Covent Garden; Messrs. HURST and CHAMBERLAIN, 31, Leadenhall-street; Messrs GRAY, ADAMS, and HOGG, Kensington, Mr. T. D. WARTHWSON, Market place, Manchester.—Northwarnborough Nursery, near Odiham, Hants.

THE BRITISH QUEEN AND PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above two new Varieties, the merits of which are thus noticed in the *Gardeners' Chronicle*. "THE BRITISH QUEEN on light soils, is the best of all kinds, and will drive Knight's Tall Marrow out of the garden." "THE PRINCE ALBERT, which has been cultivated in the Garden of the Horticultural Society during the season, produced Peas fit for the table *ten days earlier* than any other variety sown at the same time." Both varieties may be had in packages at 2*s.* 6*d.* each, at W. J. C.'s wholesale Establishment, Newerne, or the Bedford Conservatory Covent Garden.

EARLY PEAS, &c.—HENRY D. CORMACK, Gentleman, &c., begs to inform the readers of the *Gardeners' Chronicle* that they can be supplied with the following Early and Prolific Varieties, viz. Cormack's Prince Albert, British Queen and Early Kent Peas; Taylor's Improved Windsor, and Johnson's Wonderful Bean; Manchester Red and Seymour's White Celery; Walker's Long and Hamilton's Cucumber, &c., with every other variety of Horticultural and Agricultural Seeds, at his Wholesale and Retail Seed Warehouse, 100, Deansgate, Manchester.

FINE HYBRIDIZED FUCHSIA SEED.

W. MILLER begs to inform his Friends that he has spared no pains in selecting the best kinds of Fuchsia for hybridizing, and now has a few packets of fine seeds to dispose of, in packets containing 100 seeds, 7*s.* 6*d*; 50 seeds, 4*s.* Fine Verbena seed, in packets at 2*s.* 6*d.* and 5*s.* each, with directions for sowing. W. M.'s extensive list of Fuchsias, Verbenas, Pelargoniums, &c., &c. can be had on application, containing a full description of his new productions, by Dr. LINDLEY, viz.—Fuchsia "Constellatum;" Petunia "Punctata," Verbenas "Blue Queen" and "Zenana." W. M. has fine plants of his name "Fire Ball" Geranium, at 5*s.* each. The above will be sent post free to any part of the United Kingdom.—Providence Nursery, Ramsgate, Feb. 10, 1844.

CHOICE PANSY SEED.

J. FRYER begs to offer the above at 2*s.* 6*d.*, 5*s.*, and 10*s.* per packet, saved from his superb Collection, which contains the finest varieties in cultivation. Strong healthy plants are now ready for delivery, and Catalogues will be forwarded on application.

THUNBERGIA FRYERII.

Seeds of the above beautiful New Variety of Thunbergia, which was mentioned by Dr. LINDLEY in last year's *Chronicle*, and is figured in the Florist's Journal for Dec. last, at 2*s.* 6*d.* and 5*s.* per packet.

NEW FUCHSIAS.

One dozen good Show Varieties, 7*s.* 6*d*; one dozen very superior, &c. &c.

VERBENAS.

One dozen good Show Varieties, 4*s*, one dozen very superior, &c. &c.

CARNATIONS AND PICOTEES.

One dozen pair of good Show Varieties, 18*s*, one dozen pair of superior do. &c. Good healthy plants of any of the above will be sent by Post free, on the receipt of a Post-office order.—Fuchsia Nursery, Camberwell, London, Feb. 9, 1844.

DEATH OF MR. LOUDON.

THE SUDDEN DEATH OF Mr. LOUDON has involved his family in the deepest distress in every sense of the word, for although he laboured most incessantly, nearly day and night, for the space of forty years, and his works had an extensive sale, yet, from the circumstance of his being an invalid for years, and the expensive nature of the illustrations to his Works, he died comparatively indebted to the Printers and Engravers; the greater part of this debt was incurred in producing the most valuable, perhaps, of all Mr. Loudon's Works, namely, the "Arboretum Britannicum," a work which alone is sufficient to stamp his fame as unrivalled.

After much consideration, it was decided that the best means of providing for his family and a means, also, strictly in keeping with the independent spirit which characterised the life of *Mr. Loudon*, would be by promoting the sale of his truly valuable Publications. There is a large stock on hand of the following Works, the sale of which would extricate the family from their present embarrassed state, by enabling Mrs. Loudon to discharge the debt, and reserve the copyrights in her own hands as a means of future support; and it is earnestly hoped that every person who respects the memory of the late Mr. Loudon, will exert himself by soliciting Subscribers to become subscribers for the Publications enumerated below:—

Published in July, 1838, Price 10*l*., cloth lettered,

THE ARBORETUM ET FRUTICETUM BRITANNICUM;

In Eight Volumes. Four of Letterpress illustrated by above 2500 Engravings, and Four of octavo and quarto Plates.

Just published, complete in One Volume, Price 2*l.* 10*s.*, and in Ten Parts at 5*s.* each,

AN ENCYCLOPÆDIA OF TREES AND SHRUBS;

Being the ARBORETUM ET FRUTICETUM BRITANNICUM ABRIDGED, for the Use of Nurserymen, Gardeners, and Foresters.

Published October 1, 1839, in One Volume, octavo, with upwards of 350 Engravings, Price 1*l.* 10*s.*, and 2*l.* 5*s.*, coloured,

REPTON'S LANDSCAPE-GARDENING;

Being the whole Works on Landscape-Gardening and Landscape-Architecture of the late HUMPHRY REPTON, Esq.; with a Biographical Notice, and Notes by J. C. LOUDON, F.L.S., &c.

Published August 1, 1838, in One Volume, octavo, numerous Engravings, Price 28*s.*,

THE SUBURBAN GARDENER AND VILLA COMPANION;

Comprising the Choice of a Suburban or Villa Residence, or of a Situation on which to form one; the Arrangement and Furnishing of the House; and the Laying out, Planting, and general Management of the Garden and Grounds; the whole adapted for Grounds from One Perch to Fifty Acres and upwards in Extent; and intended for the Instruction of those who know little of Gardening and Rural Affairs.

Published November 1, 1842, in One Volume, octavo, with upwards of 300 Engravings, Price 16*s.*

THE SUBURBAN HORTICULTURIST;

Or, an Attempt to teach the Science of Horticulture, and the Management of the Fruit, Kitchen, and Forcing Gardens, to Persons who have had no previous Knowledge or Experience in these Departments.

THE GARDENER'S MAGAZINE;

Any Number or Volume published subsequently to 1834 may be purchased separately. The Second Series, consisting of Six Volumes, from 1835 to 1840 inclusive, for 6*l.* 6*s.* 6*d.*; for 1841, 1*l.* 1*s.* 6*d.*; for 1842, 1*l.* 2*s.*; and for 1843, 1*l.* 5*s.*; or the third series complete in 9 vols., 9*l.*

By a Post Office order being sent to Mrs. Loudon, Bayswater, London, any of Mr. Loudon's works will be forwarded in the monthly parcel of any local Bookseller; or through any Nurseryman or Seedsman in the neighbourhood of London. A list of the subscribers' names will appear weekly in the *Gardeners' Chronicle*.

A Public Meeting for the benevolent purpose of promoting the sale of these works will be held in the rooms of the Horticultural Society, Regent-street, London, by the kind permission of the Council, on SATURDAY next, the 17th, at two o'clock precisely, when it is hoped all persons taking an interest in Gardening, who are within a reasonable distance, will attend.

On the 1st December, 1843, exactly a fortnight previous to Mr. Loudon's lamented death, he published the following statement:—

"The *Arboretum Britannicum* was got up between the years 1831 and 1838, and published on Mr. Loudon's own account, at an expense of upwards of 10,000*l*., the greater part of this sum was owing at the completion of the work, but it sold so well, till the late depression of the book trade in 1841, that only about 2,500*l* of the debt remained to be paid off at the end of that year. It is, however, necessary to observe that this large proportion of the debt was not paid off solely by the produce of the *Arboretum*, but in part by the profits of Mr. Loudon's other literary property, consisting of thirteen different publications, all of which stand pledged in the hands of his publishers, Messrs Longman, for the debt due to others on the *Arboretum*. This debt, at the present time, amounts to about 2,400*l*., and hence, if 250 additional Subscribers could be got the debt would be at once liquidated, the works pledged for it set free, and Mr. Loudon or his family would enjoy the whole produce of his literary property."

"This Appeal would never have been made, had not Mr. Loudon, who has been an invalid for several years, been lately seized with an inflammation of the lungs, terminating in chronic bronchites, which, even if the disease should be considerably alleviated, will effectually prevent him from any longer pursuing his profession of landscape-gardener, on the produce of which profession, and on the literary labours of Mrs Loudon, he has entirely depended for his income, since his literary property was pledged for the *Arboretum*. Under these circumstances Mr. Loudon feels himself justified in taking this mode of soliciting additional Subscribers to the *Arboretum*, and in begging his Friends and Patrons throughout the country to assist him in obtaining them.

"The *Arboretum* has been spoken of in the highest terms in all the principal Reviews of Europe, and in the Botanical Periodicals of North America. The *Quarterly Review* says:—

"'This book is one of solid value, worthy of a place in the Library of every landed gentleman, as well as of every student of Botanical, Arboricultural, and Horticultural science . . . Let us warmly congratulate Mr. Loudon on having finished his Herculean task; a task which few men, except himself, would have had the courage to begin, and still fewer the perseverance to complete. The *Arboretum Britannicum* is complete in its kind, and it must become a standard book of reference on all subjects connected with trees.'—Oct. 1838."

The following Ladies, Noblemen, and Gentlemen, who already possess the work, on being applied to, have kindly permitted their names to be published as approving of the *Arboretum*, and of this Address to the Public:—

* It may be thought from the well known extensive sale, for the last 20 years, of Mr. LOUDON'S Publications that he ought now to be independent in consequence of too intense application while compiling the *Encyclopædia of Gardening*, Mr. Loudon fell into ill health in 1821, which obliged him ultimately to have his right arm amputated, his left hand being at the same time so much injured as to leave him with only the partial use of two fingers, and his left knee being much loosed. In consequence of these bodily infirmities, Mr. Loudon has been obliged to keep an amanuensis and a draughtsman for the last twenty years, and also, during the greater part of that time, a servant to act as valet. Had it not been for the expenses thus incurred, and for others arising from the same source, Mr. Loudon might have been now independent, even without his literary property. This explanation is due to those who are ignorant of Mr. LOUDON'S personal character.

The following Subscribers to the Works of the late Mr. LOUDON have been obtained since making up the Subscription List which appeared in the *Gardeners' Chronicle* of Saturday last:—

ARBORETUM BRITANNICUM.—10*l*.

Henry Alexander Brown, Esq. London	John Perceval, Esq., Woodlands, Ryde
P. Chalmers, Esq., Auldbar	The Earl of Burlington
Thomas Lombe Taylor, Esqs, Starston	Joseph Ablett, Esq., Llanbedi Hall

THE GARDENERS' MAGAZINE, 9 Vols.—2*l.* 17*s*.

Mr. John Lamb, Markeaton, Derby; the Vol. for 1843.

TO GENTLEMEN AND OTHERS ENGAGED IN PLANTING.

MESSRS. PROTHEROE and MORRIS are instructed by the Proprietors to submit to public competition, in consequence of the expiration of lease, on MONDAY, MARCH 4, 1844, and following days, at 11 o'Clock, THE STOCK OF ONE OF THE KENSINGTON NURSERIES, near the Great West Road, consisting of large, healthy, and well-grown Specimens of Ornamental Trees and Shrubs, of every description, Variegated and Green Hollies, Evergreen Oaks, and Cork trees, Large Fan and other Yews, twice transplanted Common and Portugal Laurels, Arbutus, Alaternus, &c., Hemlock Spruce, Pinus Laricio, P. austriaca, and nigricans, &c. &c. These Grounds have long been celebrated for the Health and Beauty of their Trees and Shrubs, and safety of removal, and well worth the attention of those Gentlemen who intend Planting in the spring. American Nursery, Leytonstone.

THE KENSINGTON NURSERIES AND THE BROMPTON PARK NURSERY, KENSINGTON GORE, having been so long and distinctively known by their respective names, in these Kingdoms, that we hardly thought it possible that one could be taken for the other; our reason for advertising as we did was in contradistinction from the other extensive and well-stocked Nurseries in the possession of Messrs. FORREST & Co. The one in question being the smallest of their Nurseries, and as the lease expires shortly, it is expected that a great part will go for building purposes. This is the cause of the Sale. Messrs. PROTHEROE and MORRIS hope this explanation will allay the fears of Messrs. GRAY, ADAMS, and HOGG.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE and MORRIS will submit to public competition at the Auction Mart, Bartholomew Lane, on THURSDAY, February 29th, 1844, at 12 o'Clock, about THREE HUNDRED DOUBLE CAMELLIAS, consisting of the best varieties, beautifully furnished with bloom buds. Also a fine assortment of STANDARD and DWARF ROSES, choice DAHLEAS in dry roots, &c.

May be viewed the morning of Sale; Catalogues may be had at the Mart; of the Auctioneers, American Nursery, Leytonstone.

VALUABLE NURSERY STOCK, IVER HEATH, BUCKS.

MESSRS. SEDGWICK AND SON have received Instructions to Sell by Auction, on the Premises, near the Crooked Billet, on Iver Heath, on Monday, February 12, at Eleven, in convenient Lots,

About 2000 fine PORTUGAL and other LAURELS from 1 to 8 feet, a very large and choice collection of standard and dwarf Apple, Pear, and Cherry trees; some very handsome New plants of good growth, Larch, Spruce, and Scotch Firs; seedling Oak and other Forest trees, plain and variegated Box, Arbutus, Privet, Laburnums, Scarlet Thorn, Lilacs, Roses, &c. &c. &c., in the Nursery adjoining the road leading from Uxbridge to Slough.

May be viewed four days prior to the sale (Sunday excepted), when catalogues may be had at the Crooked Billet, Iver Heath; at the principal Inns in the neighbourhood; at the King's Arms Inn, Oxford-street, London; and of Messrs. Snowdon and Sapland and timber surveyors and estate agents, Richmond-worth.

FUCHSIAS, VERBENAS, PETUNIAS, AND ANAGALLIS.

YOUELL & Co. beg to announce that their Catalogue of the above, with prices, will appear in the *Gardeners' Chronicle* of next week. It will be found to contain every novelty and variety worthy of cultivation, and is particularly recommended to those selecting for the ensuing season.—Great Yarmouth Nursery, Feb. 8, 1844.

LENDLE'S TANK SYSTEM of HEATING.—Second Edition.—A few copies only remain unsold in the hands of the Publishers and Author.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Feb. 14	Society of Arts	.	8 P.M.
Thursday, Feb. 15	Linnæan	.	7 P.M.
Tuesday, Feb. 20	Horticultural	.	2 P.M.
	Linnæan	.	8 P.M.

THERE is considerable difficulty to be overcome in any attempt to teach LANDSCAPE GARDENING as an art; because it is scarcely a thing to be taught, in the common acceptation of the term, but rather a thing to be sought for and brought out. There must be an inward impulse in the pupil; a quick perception of form, colour, and relative position; of magnitude; and of the harmony of things in general; and all this is no less necessary in the teacher. Besides, according to our idea, Landscape Gardening is not a thing to be taught, even to those possessing the necessary talent, without a direct appeal to Nature.

A certain amount of materials is given to be worked upon, and the question is how to make the most of it. But unless the materials be present to our senses, it is impossible to point out the various means by which they may be made available to the utmost extent. We have the dead flat—the undulating surface—the hilly, the mountainous, and rocky country, and endless mixtures and modifications of these, and of land and water. We have not merely one window to look from, but many, having various aspects; and innumerable points of view out of doors, to consider. The matter which requires the greatest skill is to contrive to make one thing serve many purposes—one tree or bush to fall in with advantage to many points of view. It will be asked who is to judge of the propriety of arrangements suggested by a teacher? How is a pupil to know and feel that his master has good taste? It is obvious that the arrangements, when made, indicate the taste of only one individual in the first instance, and that the result of his labour can be valued only by those who are similarly constituted by Nature; so that it is possible the pupil may despise the taste of his master, justly or unjustly. Fortunately, those who have no generality of taste, so to speak, learning from others that such and such things are admired, get into a habit of taking for granted that all similar, or nearly similar things are to be admired; that every domain belonging to a Peer or wealthy Commoner must be magnificent; that wherever big trees stand—wherever there is water, still or noisy—wherever rocks and hills—extasy ought to be expressed; and thus the multitude comes to believe itself pleased and delighted, and the owner of the fine things chuckles at the thought of his being lord over all.

We have seen (according to our own notions) very good artificial landscapes made out of indifferent subjects, and tolerable subjects made hideous by attempts at embellishment. We have seen admirable subjects spoiled, others rendered splendid. Though we have had to deal with some of the best subjects in Nature, and found our work admired (whether the admiration was real or feigned matters not), we are not so conceited, nor so ignorant of the constitution of human nature, as to set our taste up as a standard. We have often had to revise our own work, and to make corrections and additions; and some painful necessity has occurred to us in our time (which has not been very short)—such as that of felling a fine tree, because, though, while young, it performed an important part, it had grown too large for its station in the landscape.

We have said enough, perhaps, to show that what is called Landscape-Gardening cannot be taught in the closet; and, though rules have been laid down on paper, that they cannot be applied with any degree of certainty. *Poeta nascitur, non fit.* So must it be with a landscape-gardener. We do not affirm that the profession is not needed; it is a useful one, provided he that practises the art has a love for it. It requires more various talent than almost any other profession; and were we to appeal to a Phrenologist, he would probably enumerate more than half-a-dozen faculties which would have to be in a state of strength and activity. A young person inclined to follow this profession should be taken to see Nature in all her aspects; and from her he should take all his lessons; for this reason, that the Creator has adapted Nature to make agreeable impressions on our faculties, as well as to excite some emotions which warn us of danger, and others which rouse wonder, awe, and gratitude to their Author. He should draw well, so as to be able to accumulate examples, which he may transfer, as his judgment may direct, to any portion of country he may be called upon to adorn. It is a duty to the public to be performed by every proprietor of land who is conscious he does not possess talent for rendering a district agreeable to the eye, to look out for some one who does possess it, and whose assistance he should require. We can only advise those who have country residences and good talent to look well about them, and to direct operations themselves. Unhappily, we cannot exhort against self-conceit, which is too often present, and in the way of talent. Happily, we have in our country the display of a vast amount of fine taste. Good examples are so numerous in every style, that no one need travel far to find them. One thing, however, has often annoyed us—viz., the shutting out of beautiful views by plantations along the highways: there should be an Act of Parliament against this.

Architecture is, in an intimate degree, connected with Landscape-Gardening. Into this department, however, we do not wish to venture far. We may remark that style should be adapted to situation, and also to what is sadly neglected—to time. It is surely incorrect to associate our peaceful days with strong towers and battlements—with the appearance of defences against weapons no longer in use, and which the meanest of the modern implements of war could prostrate in a moment. Still more preposterous is it to connect such things with modern windows, and every means of easy access. Modern architecture has run wild in attempting to mix different styles, and to accommodate them to each other. Fancy has extended her skill to the abodes of the brute creation, and rendered them as classical as those of men. Not having been rich enough to build more than a cottage on a large scale, we felt, on approaching our rather pretty domain with a stranger, somewhat queer when he asked, "Are these your stables?" Not a word was said of the fine landscape that burst upon his view. Nevertheless, our friend got reconciled to the accommodation afforded to him in the supposed stables; and so we had to thank him for giving us an additional example of variety in human idea and human perception. We decline going farther into this part of the subject, which looks too like a labyrinth; and we have no desire to be the cause of our kind readers losing themselves.—*G.*

How best to PRESERVE THE VITALITY OF SEEDS in long sea-voyages is one of those problems which experience alone can solve, but which is of such very great importance that it has already received some attention at our hands (p. 787, for 1843). Lately, a new idea has occurred to Mr. James M'Gall, a young man who was sent out to the Bermudas a few years ago as gardener, and who is now in the employment of Colonel Reid, the Governor, to whom we are indebted for his observations.

In the Bermudas there are sudden and violent changes of climate, caused by the dry winds of the north shifting to hot southerly winds, bringing an atmosphere loaded with moisture. In consequence of this there is a great difficulty in preserving seeds, which, although they spring luxuriantly before the middle of summer, immediately afterwards lose their germinating power.

Bottles carefully sealed, and thick brown-paper packages are generally employed for their preservation, and are kept in a cool and well-aired room. But although this preserves them very well from insects, yet the advantage does not appear to extend further. In the beginning of May last, Mr. M'Gall was induced, from the evenness of the temperature there, to put a bottle of Onion-seed, carefully sealed, which had arrived at Bermuda from Madeira in the beginning of February, into the bottom of a cistern of rain-water five feet below the surface of the earth. The cistern was cased with Roman cement, and had a free circulation of air above the cement, about seven feet from the bottom. On the 1st of November, about the usual time of sowing, this bottle was taken out and its contents sown, together with those of four other bottles of the same package, which had been kept in a cool warehouse during the summer, and of three others. In all cases the seed came up more or less; that in some of the bottles to the extent of about a fifth part, others of about a tenth, but in some scarcely at all. The seed, however, which had been kept under water came up regularly, and four or five days sooner than the others; the plants were strong, and not more than a fifth part of the seed failed. The seed in three of the bottles looked pale when opened, and several seeds were chipped or broken; the fourth bottle, in comparison with that taken out of the water, seemed equally fresh, though very few seeds sprung. It is no doubt possible that some of the seed was not good when first imported; but be that as it may, the seed kept under water came up as quickly as new seed.

This is a new, and we think an important fact; because, if further experiments confirm Mr. M'Gall's experience, it may possibly be found that the best plan for seeds on board ships bound to distant countries, is, as Col. Reid has suggested to us, in bottles plunged in ships' tanks, where they may be exposed to a more uniform temperature than can be otherwise secured.

We throw this out for the consideration of the importers of seeds.

BEES.—No. VI.

(*Continued from p. 69.*)

The Pasturage of Bees, and the Transporting of them to it.—Some counties abound in honey more than others. The three counties, Lanark, Ayr, and Middlesex, in which we have lived, are "flowing with honey." Other counties may be compared with these. Bees will thrive where most of the following plants are found:—Sallows, Gooseberries, Plums, Apples, Pears, Planes, Limes, Furze, Broom, Field Mustard (Sinapis arvensis), common Bird's-foot Trefoil (Lotus corniculatus), greater Bird's-foot Trefoil (Lotus major), Beans, Dutch (white) Clover, Ling (Calluna vulgaris), and Devil's-bit Scabious (Scabiosa succisa). There are many more honey-producing plants, but they are either not native, or not allowed to flower extensively in the counties which are mentioned above. If honey-plants do not grow in the immediate vicinity of an Apiary, the Bees therein will not—cannot, gather much honey, for they have not only a greater distance to fly, but are sometimes on their journey overtaken and destroyed by sudden showers. In many parts of Scotland, and I dare say of England too, Bees are transported from one pasturage to another. This cannot be too highly recommended, and I think I cannot do better than mention how, when, and whither, the Bees at Carluke are removed. Carluke is situated three miles north of the Clyde, which runs through the centre, and drains the greater part of Lanarkshire. About three miles to the north-east of the village there is a large track of land densely covered with Ling, or Heather, as it is there called. About the 1st of March the stock-hives are removed on very light hand-barrows to the banks of the Clyde, which abound with Sallows, Gooseberries, Plums, &c. At the swarming season many are taken back to Carluke, and from the 1st to 12th of August all are removed to the Heather. In removing Bees it is necessary to ventilate the hives by raising them off the boards with thin wedges or penny-pieces, and by placing hair-combs or pieces of perforated tin on their mouths. Those Bee-keepers who say that ventilation is necessary at any other time do not know much about the habits of the Honey-bee. Wm. Rettie grew's best top swarms gathered, as we have heard, 50 lbs. each in the month of August last year; that is to say, while they were on the Heather. In answer to a question, he says—"I do not believe that they would have gathered 20 lbs. if they had not been taken to the Heather." And in a letter of Sept. 12, 1843, he says—"A friend has a hive, that gathered 15lbs. on the 5th, 6th, and 7th of this months and during the last seven days one belonging to another person gathered about 28 lbs. or 30 lbs." None of mine have gathered so much—only one has gathered 22 lbs. during the same time. The honey is now mostly collected from the Blueheads (Devil's-bit), which are not very plentiful where my hives are; but I will remove a few of them on the first opportunity. The month of August this year was unfavourable here; but I never saw Bees collecting honey in quantity so far in September before this year." In unpropitious or rainy seasons, hilly and exposed pastures are best for Bees—there they will collect honey; whereas, if placed in a valley or sheltered situation, they eat what they have collected, or what is given to them. It may be interesting to gardeners to know that flowers give or contain the greatest quantity of honey when the wind blows from any point between south and west inclusive. This will not appear strange to those who have paid attention to what is said in the third chapter of the second Book of "Lindley's Theory of Horticulture."*—*A. Pettigrew, Wrotham Park, Middlesex.*

(*To be continued.*)

A KNOWLEDGE OF PRINCIPLES ESSENTIAL TO THE BEST CULTIVATION.—No. I.

As the cultivation of plants in pots admits but a limited amount of material for their growth, it may be inferred that any system involving such a restriction, and consequent exposure to extreme fluctuations of temperature, can only be productive of a partial effect, compared with their condition in a state of nature. At p. 876, 1843, it is stated that "Nature has given plants the power (under favourable circumstances) of producing from the bosom of each leaf a branch, which is capable of being rendered subservient to the formation of bloom; and that the proportion of bloom will, as a general rule, be in proportion to the multiplication of such branches, subject to their being produced within a given period prior to the season of bloom, and being duly exposed to the agencies which are essential to maturity of growth."

Assuming the correctness of these conditions, the following inferences are drawn:—

1st, That perfect cultivation necessarily involves the greatest extent and vigour of growth of which plants are capable;

2dly, That such a growth is the only test of their average proportions in a state of fertility;

3dly, That maturity of growth [illegible] be antecedent to, or uniform with, [illegible]

* Though this book cannot well be recommended, yet it is scarcely to be [illegible] journeymen gardeners. To such it is [illegible] on gardening in the English language [illegible] work will induce many young men

The absence of fertility in plants, generally, may be attributed to an imperfect application of the agencies (whether in excess or deficiency) which are essential to its formation. The following case will illustrate this:—Two years ago the writer forwarded a duplicate of the beautiful Leonotis Leonurus to an eminent cultivator, and in the autumn the same cultivator thus writes:—"I have Leonotis in splendid growth, and also Fuchsia corymbiflora, the latter 10 feet high, but without any appearance of bloom on either; what is the cause?" The reply was—"Both are attributable to one cause, viz., an undue excitement, either by organic or atmospheric stimulants, thereby causing an excess of growth beyond the season of bloom."

What Dr. Johnson has well observed in respect to human nature, that it "is everywhere made to furnish the machinery which may work most effectually upon itself," may be equally applied to plants,—that they, too, (when understood in the relation which their organic structure bears to the agencies which sustain them,) best afford the knowledge which may most effectually be rendered subservient to their perfect culture.

In accordance with these views, a principle is given at p. 787, 1843, as follows: An accurate acquaintance with the physiological or organic structure of plants is of essential importance to a knowledge of the nature, extent, and application of the agencies which sustain them.

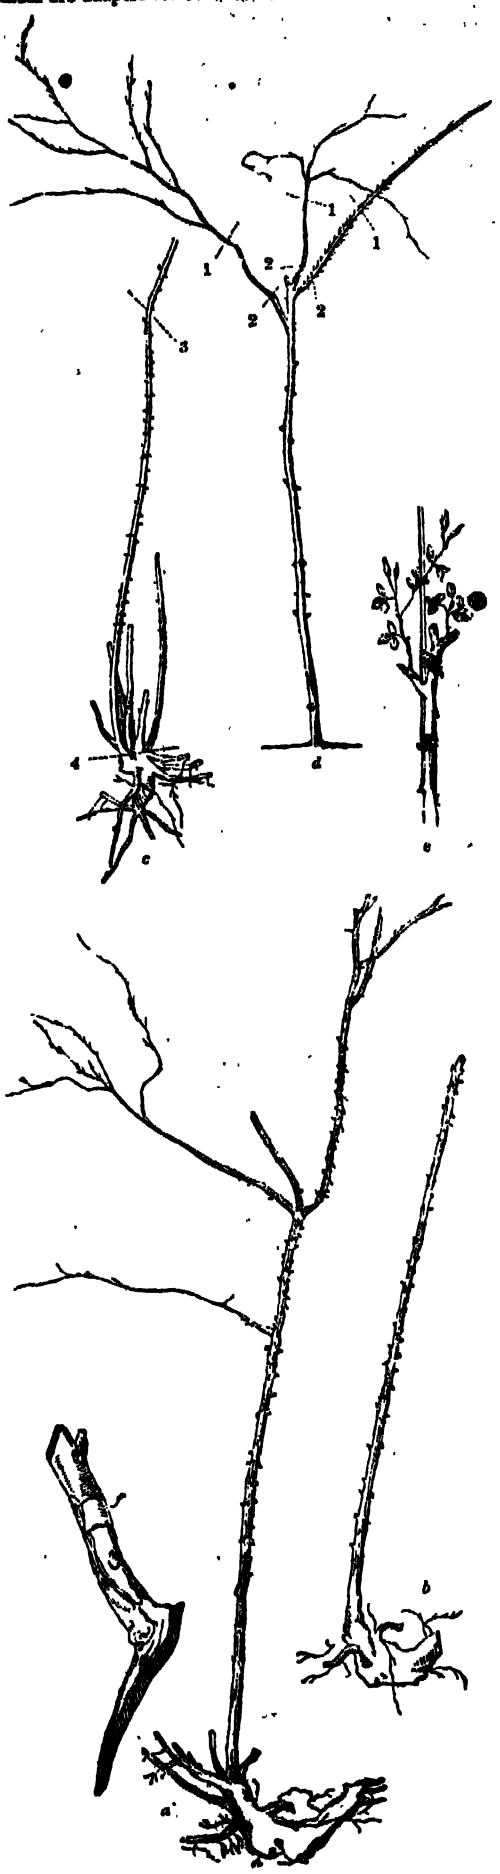
Every fact, whether derived from observation, analogy, or practice, favours this conclusion. If our present knowledge has put us in possession of the means of approaching more perfect growth in any department of Gardening, it only remains that the conditions which operate upon the productive organs of plants throughout their respective stages of growth should be duly applied, to render such growth subservient to its ultimate object of fertility.

As "every leaf-bud has its own distinct system of life and growth," and also, as every plant is individually "a collection of a great number of distinct identical systems of life,"* it follows that a system of cultivation is perfect, in proportion to its capability of causing a development of the greatest number of leaf-buds into branches, and *vice versâ*.

Again, by the laws which govern the productive organs of plants, "all flower-buds are analogous to leaf-buds," and "whatever are the laws of the arrangement of branches, with respect to each other, the same will be the laws of the arrangement of flowers, with respect to each other"†; therefore it may be inferred that as the formation of leaf-buds is a predisposing cause to the production of flower-buds, the most perfect system of cultivation will be that which produces the greatest number of systems of life (in the highest vigour), by the production of leaf-buds, subservient to the formation of bloom.

One of the most common errors as regards the formation of bloom in plants, is a notion that they must be necessarily restricted in the proportion of soil, or size of the pot in which they are grown; this mistake is founded on a forgetfulness of the various abilities of cultivators, the skill of whom may so far differ that in one case a plant may be so treated as to require the space of a 16-sized pot, while, by inferior management in other hands, a similar plant might not occupy more than a 32. A plant in a 16 or 12 pot may be as effectually restricted (as regards the unfolding its bloom) as another in a 48, if the growth, in both cases, be produced by a given period prior to the season of bloom.—*William Wood, Pine-Apple Place.*

(To be continued.)



THE ROSE GARDEN.—No. IV.

(Continued from page 68.)

The most promising plant to be taken for budding upon, provided size can be obtained, is a well-ripened and woody sucker of the present year, whose root will almost always admit of being trimmed and placed within a plunged pot, for the purpose of avoiding a check on the subsequent removal of the plant when become ornamental. Next to this (if not equal to it), a plant of the preceding year is to be preferred for the same reasons and with the same advantages. For free growers, however, stocks of the 2d or 3d year should be preferred, as less likely to be cut off by frost, and being also more capable of self-support. There seems a question, also, if these be not more vigorous, care being taken when worked that the buds entered are neither sluggish nor delicate in their habit of growth; such buds should invariably be entered upon young and succulent stocks.

In choosing young and rather slight stems, care should be taken to select such plants as are woody, and tolerably able to support themselves and defy the frost; these should be sought amongst the shoots of grey, brown and green, or rather grey and green striped, which eventually run to a large size, and are particularly clean and healthy in appearance; and green suckers from them may be readily obtained of good size, and of the height of ten or twelve feet. Without this precaution there is some danger of an unexperienced person mistaking the small for the large sorts, and the quantity of pith some of the former contain, render them liable to rot down, on accidental exposure of wounds, &c., and their general want of vigour makes the possession of them undesirable.

There are two varieties of the Wild Rose most peculiarly under working, both suffruticose or half-shrubby, and both slight in the stem; the one grows upon a most prolific root, which throws up innumerable suckers, looking almost like a tuft of Rushes, and as far as the number of plants to be obtained by the division of one stool may go, a most desirable prize to the collector; the other similar in colour and pithiness; but whereas the first is dwarf and bushy, the second produces few suckers and climbs to the height of 20 ft. or more, but neither of them are adapted for standards.

c A stock of the Wild Briar as brought from the hedge.

b The same stem, the roots and head having been trimmed for planting.

c Another plant, with younger and more vigorous roots; the dotted line indicating the passage of the saw in the removal of superfluous wood.

d The stock B., with the shoots made during the summer, and the buds entered in August.

A plant is not to be rejected on account of its age, as unconnected with its appearance, youth being by no means a sine qua non in the collection of stocks. A sucker just ripe and a plant in its third season frequently proving equally vigorous after transplantation; but one thing must be attended to, viz., that the stocks be free from side shoots, the removal of which mangle the stem and spoil the appearance of the future tree; but if these be unavoidable, care should be taken to remove the branch desired, by a clean cut quite to its base.

1. The branches shortened in November.

2. The branches cut back to the sap-buds in spring.

e The same plant the succeeding summer; one bud having failed, the branch has been cut away, and the other buds are figured as flowering.

f A side-shoot of the Wild Briar, with an inserted bud, previous to its opening; the sap-bud above it being on the eve of bursting.

The Wild Rose displays so much variety in its mode of growth, colour of bark, shape of stem, formation of root, &c., that any attempt to convey an adequate idea of these by figuring, would alter the nature and intention of this work entirely. The accompanying engraving will give a distinct idea of the plant in its progressive stages; the frontispiece being intended to represent its completion.

FAMILIAR BOTANY.

Morphology.—No. II.

Ὅθεν τῶν φύλλων μεταγραμματισμοὶ καὶ ἕτερον πάντα· ἴσως γὰρ τὰ μὲν πρότερον, ἕτερα τυχηρὰ φυόμενα τῶν ἀεὶ, ἕτερον ἀπεργαστικὸν ἦν, καθάπερ ἀνθέων ἐστὶ φύσις. τούτων δὲ ΟΥΤΡΑΔΙΟΝ ΤΟ ΑΠΑΟΥΝ Η ΤΟ ΠΟΑΤΕΛΕΣ. ΑΣΘΕΝΗΣ ΔΕ Η ΑΡΧΗ.—*Theophrastus de Causis Plantarum* II. 2.

Principium florum et foliorum idem est.—Linnæus.

When the Greek philosopher declared that nature always proceeds from imperfection to perfection, he is thought to have distinctly announced the principles upon which Morphology depends. There is not, however, such further evidence in what remains of the works of Aristotle, as entirely justifies our admitting more than the existence in his mind of some perception of its truths. It is his pupil, Theophrastus, who has distinctly shown in the words above quoted, that by him, at least, the order of formation in plants was clearly appreciated, and that complicated forms are in all cases, and of necessity, the result of simple forms. "The common transformations of leaves and other things is manifest. In the Croton leaf, for instance, some which grow round in the beginning, afterwards become angular, as if completing themselves. For simplicity is easier than what is complicated. THE BEGINNING IS STRENGTHLESS." To be sure it is. Infancy is weak, whether in the structure of the globe, or the organs of plants, or the fabric of man. It was only as strength was gained, and power acquired, that gaseous emanations were consolidated into rocks in the creation of this planet. It was only as the climate of our earth became fully adjusted that the simple forms of plants and animals were increased by the addition of mammals, trees, and highest beings. The insect is still feeble in the grub, the bird in the egg, the quadruped in the fœtus, and the plant in its seed. All by degrees clothe themselves with organs, having a common origin, but mere attempts at structure in the beginning; and all, by gradual changes of the elemental forms of organisation, rise into perfection. In every case *the beginning is strengthless.*

The high philosophy of the Greeks expired with their so-called liberty, and fell into a slumber of nearly 2000 years. It was not till the sixteenth century that the great views of the school of Aristotle met with men capable of comprehending them, and more than two centuries again elapsed ere their doctrines began to assume a definite form. In 1583 Cæsalpinus, an Italian Botanist, spoke of the origin of the parts of plants, and alluded obscurely to the common origin of them all; but it was reserved for Linnæus to give life and reality to the far-seeing doctrines of the Greeks. In the year 1759, he maintained that all the organs of plants are of the nature of leaves, and that the various floral organs are only so many *anticipations of foliage*; that is to say, leaves that have not time enough to grow into their proper form. The year after he published his famous "Prolepsis Plantarum," in which he explains his theory in ample detail. Let us see what he says:—

"As soon as leaves have expanded themselves in spring, a bud is observable in the axil of each. This bud swells as the year advances, and in time becomes manifestly composed of little scales: in the autumn the leaves fall off, but the bud remains; and in the succeeding spring swells, disengages itself from its envelopes, and becomes lengthened: when its outer scales have dried up and fallen off, the inner ones are expanded into leaves (like the wings of a butterfly emerging from its pupa), which separate from each other by means of a gradual extension of the young branch, and presently each new leaf is found to contain in its bosom a little scaly bud, which, in the following season, will also be developed as a branch, with other leaves and other buds. Now, when I see a tree adorned with leaves, and in the bosom of those leaves provided with its little buds, it is natural to inquire, of what do these buds consist? Do they consist of the rudiments of leaves with their gemmules, the latter of other leaves and buds, and so on to infinity, or, at least, as far as the extension of the plant is likely to proceed? Nature organises living beings out of such minute particles, and even from fluids themselves, that the best eye may in vain seek to penetrate far into her mysteries."

"If a plant, which has flowered and fruited for many successive years in a pot, is transferred to a rich soil and warmer station, it breaks forth into branches instead of flowers. Hence it appears that branches and leaves can be produced from the provision made for flowers, provided circumstances are favourable to their development."

"As to *buds*, 'the bulbs of Hyacinths and Ornithogalums afford good evidence of their nature. Both bulbs and buds are winter coverings of plants, with this difference, that bulbs are the bases of leaves of the previous year, while buds are the rudiments of leaves of a coming year. Wherever bulbs grow, there are formed the persistent bases of leaves, within which young leaves are to be developed: within these latter leaves repose the buds or rudiments of future plants, exactly the same as the buds of trees. These buds consist of the rudiments of leaves of the succeeding year; small indeed, but containing in their axils other

* "Principles of Horticulture," p. 112, 113.

† Lindley's "Principles of Botany."

rudiments of a like nature. Now, if it happens that such a plant flowers, the bud, which would otherwise have produced leaves the year after, is converted into a scape a year earlier; whence it comes to pass that the rudimentary leaves lying in the bud lose a part of their nutriment, in consequence of the sap being drawn off to the fructification: wherefore those leaves continue small, assume a different structure, easily wither, and are called by botanists bracts. Thus bracts are nothing but leaves which would have been developed another year if the plant had not flowered.'

"As to the *calyx*. 'That the calyx is only the approximated leaves of a plant, is apparent from several instances. The calyxes of Pyrus and Mespilus are often expanded into perfect leaves; the Rose offers a similar instance of the change. The leaves of Mesembryanthemum barbatum are supplied with a most curious apparatus of hairs; and the calyx consists of five pieces, in all respects similar to the leaves of the stem. The calycine leaves, indeed, are often very small, juiceless, and different from those of the stem, as if scales of buds previous to their developement; but that they still are nothing but leaves of the same nature as those of the stem, must be concluded from this, that when plants, Rosa and Geum rivale for example, become, in consequence of excessive nutriment, proliferous, the calycine leaves, which before were small and dry, expand into leaves in size, colour, figure, texture, and substance, exactly like those of the stem. Hence it is not to be doubted that the calyx and the leaves of the stem were in the beginning alike.'

"As to the *petals*. 'It is often very difficult to distinguish them from the calyx. The white corolla of Helleborus niger, after flowering, assumes the green appearance of the calyx. In luxuriant flowers of Rosa and Geum, the corolla sometimes becomes wholly green, and assumes the foliaceous nature of the calyx. As the calyx is nothing but leaves, and as each leaf contains in its axil the rudiment of a plant consisting of the rudiments of leaves of a future year, it follows that the petals are of necessity the rudiment immediately within the calycine leaves; the petals, therefore, would have been leaves another year, if flowers had not been produced.'

"As to the *stamens*. 'From double flowers it is apparent that stamens do change into petals and petals into calyx. This is so well known that it need not be insisted on. Now, as from the axil of every leaf arises the rudiment of a plant, and from the axil of the calyx are produced the petals, which are nothing but more tender leaves, and as these petals must have, like other leaves, the rudiments of leaves in their axils, it follows that stamens are so, for they can be transmuted into petals, as the petals can into the leaves of the calyx.'

As to the *pistil*. The evidence of this being also reducible to leaves, is taken from a change observed in the flowers of Cardnus heterophyllus and tataricus, in which the style was changed into two green leaves like bracts, and from the common conversion of the pistil into leaves in proliferous individuals of the Rose, the Anemone, and others.

This is enough to show in what way the great Linnæus regarded this curious question. I shall next explain how others have improved upon his views.—*R. E.*

THE MISTLETOE.

In the days of the Druids, this parasitical plant was supposed to have its attachment principally to the Oak-tree. The Celtic priests regarded it with extreme veneration, and collected it for charms, and cures, and religious ceremonies, with solemn formalities; but with them it owed all its supposed mystic influences to its connexion with the sacred Oak.

I am led, however, to imagine, from recent inquiries and some personal observation, that we do not know the true Mistletoe of Celtic superstition, and therefore that Pliny, the naturalist, though he was contemporary with the Druids, may have in some way mistaken the plant. He probably took his report on trust. It may not have been a production of his climate, he may have had no opportunity of observing it himself. We know that most of the names given by him and Theophrastus have been rejected by modern botanists, or have been applied to other plants; as the Daphne, which was the Laurel of the Greeks, is not our Laurel. Virgil speaks of the *Viscum*, which we suppose to be the Viscum album—

> Quale solet sylvis brumali frigore viscum
> Fronde virere novâ, quod non sua seminat arbos,
> Et croceo fœtu teretes circumdare truncos;

but without any direct allusion in those lines to the Oak or any particular tree as its nurse, though he certainly refers to the Ilex in the course of his metaphor, a few lines further.

M. Bataille, the Curator of the Botanical Garden at Avranches, in the Department of La Manche, Normandy, has favoured me with some interesting notes on the subject, which have led me to examine Oak forests, and various plantations in that district, the examination of which tends to corroborate his remarks. He asserts that in all his botanical researches throughout the arrondissement, he has never seen the Mistletoe growing from the Oak, nor been able to discover that any other person had seen it on that tree, though it is common on the Apple-tree, the Hawthorn, and many other of those trees on which the thrush (which is believed to be the agent of propagating the plant) had voided the undigested berries of the Viscum album on which it had been feeding. Thus, by a beautiful provision of the Creator, that matter which otherwise would fall barren to the earth and perish there from want of the peculiar element which had been placed in the bark of certain trees for the development and nurture of the vital principle within it, is rendered serviceable. The consideration of the extent of injury which this parasite occasions to the trees which it tends to exhaust, is beside the question under consideration. But we may conclude with Sir John Colbatch, "that this beautiful plant has some important properties, and that it has been designed for further and more important purposes than to feed thrushes, or to be hung up surreptitiously in houses to drive away evil spirits."

The Druids occupied the forests in Normandy and Brittany: if, then, the Mistletoe with which we are now so familiar, and which is naturally growing at this day on the Acacia, the Hawthorn, and the Poplar, in the botanical garden which is under the care of M. Bataille, be the same as that which the Druids venerated, and which is believed to have been the companion of the Oak, how does it happen that the one has since repudiated the other?

M. Bataille states that after consulting the works of many of those botanists who have given the description of the plants of France, he has found that the authority of Duhamel alone is urged to prove that the Mistletoe may be brought to grow indiscriminately on any of the indigenous trees of the country and on many exotics, in opposition to which Thuillier,* who describes this ligneous parasite accurately, says, that it is found on almost all trees except the Oak.†

M. Bataille planted an Apple-tree among the Honeysuckle tribe in the Avranches garden, and in the part of the tree where Mistletoe would be most likely to establish itself, he inserted in the bark some of its berries; these germinated, the radicles stretched out and fastened upon the bark, on which they continued firmly imbedded during the summer and winter without farther apparent progress. It was not until the succeeding spring that they gave any signs of life, in throwing out a few little branches furnished with the elements of leaves.

M. Bataille has repeated experiments of the same kind with Oak, but unsuccessfully. However, he is about to renew them, in the expectation of ascertaining whether it has much disposition to nourish the Viscum album or not. —*Martin Doyle.*

* Author of La Flore Parisienne.

† There is a branch of Oak with the Mistletoe around it preserved in the Museum of Paris: it was not considered a rare production for it a law to forbid not its being so preserved.—M. D.

Home Correspondence.

Burnt Clay.—I can fully confirm the statement of Mr. W. Paul, of Cheshunt, which appeared in the last week's *Gardeners' Chronicle*, as to the good effects produced in gardens, where the soil is strong, by the use of burnt clay or marl mixed with the ashes of vegetables and the charred branches of trees. I have had for some time past several of these burning heaps in the environs of my garden, which produce us in succession a very valuable manure; they are easily kept in a state of combustion, and all the care they require is, to cover and surround them occasionally with fresh clay or marl, that they may not burst out into an open flame. My gardener sowed two beds of Onion-seeds of the Globe, James's Keeping, and Strasburg sorts, mixed together, about the 10th of March last, with 1 lb. of seed to each bed. The beds were each of them 18 yards by 12 yards, and one of them was manured with good stable-dung; the other by this mixture of burnt clay and vegetable ashes. The produce of the first did not exceed five bushels of an inferior size, the greater part having been destroyed by the larva of the Onion-fly; whilst that of the latter was 20 bushels of Onions, as large as those imported from Portugal. Another remarkable circumstance is, that the former have not kept well; but the latter are as sound as possible, not a single bulb in the strings showing the least appearance of decay. The same burnt mixture has been applied with equal success in my fruit-garden. I had observed a great decrease in my crop of Apricots for several years past, and upon a careful investigation as to the cause, my gardener and I agreed that it must be owing to the tenacity of the border; we therefore had the old soil removed, and a quantity of this burnt mixture with a little fresh loam substituted for it. My gardener planted the border so renewed with runners of Keen's Seedlings, in rows; they became strong plants by June, when they flowered and produced an abundant crop, and all my Apricot-trees were covered during the summer with well-ripened fruit. I am so fully persuaded of the excellence of this kind of manure, that I intend to adopt it generally on my farm. It will there have a double advantage; for I shall be enabled to save the farm-yard dung for composts, and I shall have the gratification of seeing my hedges neatly trimmed and my ditches well cleared out. Our stiff soils will be also rendered more friable, and will not suffer as they now do from the retention of wet on the surface.—*Oswald Mosley, Rolleston Hall, near Burton-on-Trent.*

Durability of Oak cut in Winter.—We have a saying in Surrey, that the sap of winter-fallen Oak is as hard as the heart of that which is thrown in the spring. There may be a little exaggeration in this saying, but it serves to show the common impression of the comparative durability.—*A. C. P.*

Raising Seedling Picotees.—Wood's Col. Steel, red Picotee—from three seedlings out of this flower, three red Picotees were produced, one of which was just admissible on a stage. From Hufton's Isabella—I had about thirty plants, many of them were very large and showy, both red and purple Picotees, were well-formed, and made handsome border-flowers; but they were either serrated in a slight degree, or somewhat horned. Lee's Cleopatra—from forty plants of this none were good. From Ely's Criterion, red Picotee, were seven plants, one very capital red Picotee, not single red ditto, one dark self, and four rose pink bizarres. From Ely's Grace Darling, purple Picotee, were also seven plants; one excellent, one middling, three with round useless pods, purple Picotees with light edges, two died. Same sort sowed in November produced sixty plants, but none good. From Sharp's Nymph of the Nore, red Picotee, I had two plants; one was a self, the other a red Picotee, with the narrow petals of the parent; otherwise, first-rate. From Hufton's Nebemiah, I raised three plants, viz., two purple Picotees, of which one was tolerable, and one purple self.—*O.*

Cucumbers.—The accumulation of steam in Cucumber-frames about this season is often injurious to the plants. To obviate this I caused a bed to be made of well-prepared horse-dung and Oak-leaves, for a two-light frame, having a partition in the middle, and forming, as it were, two single-light boxes. Each was subjected to the same treatment with regard to fermenting materials; the bed was raised high in order that a good front lining might be applied, the end and back were well thatched with straw to keep out frost, wind, &c. The bed being made, and the boxes placed on it, the seeds were sown in one of them; when these began to vegetate, I found it necessary to supply a lining, and at the same time I introduced a tin pipe, six feet long, and two inches in diameter, placing it longitudinally, but in a sloping direction, in the front of the frame, with the lower end protruding through the lining, near the ground, and the upper entering the bottom of the frame, thus causing a draft of air through the pipe into the frame, the effect of which was not only to raise the thermometer 10° or 12°, but to expel the damp and dry the soil, so that after the plants were potted, I found it necessary, notwithstanding the very cold damp weather, to water daily; and in about three weeks I had a good stock of strong healthy plants. With a view to test the advantages of this treatment, some of the plants were placed in the adjoining frame, which was prepared in the same way as the one they were raised in, with the exception of the air-pipe. Having a good stock of plants, three pots of the best were selected; but although the frame was previously replenished with a lining, and every care taken to preserve them, at the end of a week they perished for want of heat. I then introduced an air-pipe into this frame also, and planted more plants, which flourished through the season with the best results; thus proving to my satisfaction the utility of air-pipes. Much, I imagine, may be effected by this mode of heating, not only in growing Cucumbers, but other plants, where there is a good supply of fermenting materials.—*M. Power.*

Cause of Hardiness.—The difference between hardy and tender plants arises from their capability of taking up chemical substances, alkalies, acids, or earths, by which the juices are kept in a more or less fluid state. In tender plants they become thickened, and are not capable of passing up the vessels at a comparatively mild temperature, and if the temperature is reduced the plant dies, in consequence of the juices becoming congealed. In hardy plants these remain fluid at a very low temperature; if they were to become frozen they would expand and burst the vessels, and death would be the consequence. Plants the most succulent, and apparently very tender, stand severe frost (Scilla Sibirica for instance), while trees, to appearance quite hardy, are destroyed by it. The hardiness of a plant does not depend upon woody fibre, as death in all cases proceeds from the juice expanding and forcing the bark from the wood. Perhaps this notice will lead the Chemist to analyse the juices of hardy and tender plants with a view to determine their different properties, in order to ascertain if it is possible to render plants hardier by giving them substances which will keep their juices fluid, and make them less liable to the effects of frost. In acclimatizing plants, little alteration has taken place in the constitution of any particular species or variety, beyond the capability of its taking up more of the substance, whatever it may be, which renders the juices thinner, and makes them susceptible of the action of frost. Can there be any latent caloric in substances taken up by plants which is afterwards given out to them?—*H. Groom.*

Slugs.—I have a few Cauliflower plants which were much eaten by slugs. I put a small one-light frame over them to protect them from frost—any access from without seemed improbable; nevertheless, when I searched I found a great many slugs; whenever I lifted up some pots of Strawberries within the frame, I always found two or three large ones. I conclude that they have been for some time buried some depth beneath the surface, and perhaps their habit is to lie deeper than is generally supposed.—*J. W., Peterborough.* [Pretty strong gas-water applied to ground infested with slugs at their feeding time kills them effectually.]

Digging Vine Borders.—In many places Vine borders are dug, and an early crop of Cauliflowers taken from them, or they are planted with annuals and greenhouse plants. This is a practice which every gardener should condemn, for it cuts all the roots near the surface, which is a serious injury to the Vine; as the surface-roots are capable of receiving more nutriment from dung laid on the border than those at a greater depth, and in proportion as the surface-roots are destroyed or damaged will the crop be scanty.—*J. W. K.*

Mr. Loudon.—As I find that a passage in the Advertisement on our behalf, which appeared in the *Gardeners' Chronicle* of Jan. 27, has led to an erroneous impression with regard to Messrs. Longman, I shall feel very much obliged by your allowing me to make the following statement. The fact is, that though all the works, which were poor Mr. Loudon's own property, do "stand pledged" in the hands of Messrs. Longman to defray the debt on the Arboretum, &c., those gentlemen hold the books solely as trustees, to receive their proceeds,

sent to pay the amount in equal shares to the printers, engravers, and wood-engravers, who are the creditors to whom my late husband was so largely indebted. I am most anxious to make this statement, as I have experienced the greatest kindness from Messrs. Longman, who have done everything in their power to alleviate the painful circumstances in which I have been placed.—*J. W. Loudon, Bayswater, Feb. 7, 1844.*

Mrs. Loudon.—It gave me much pleasure to see in the last *Chronicle* that the meeting in behalf of Mrs. Loudon, kindly permitted by the Horticultural Society to take place in their rooms, was finally fixed for Saturday, the 17th inst., when I trust some effectual means will be adopted to relieve Mrs. Loudon and family from the present position their affairs assume, and enable them to reap unalloyed the benefits arising from the late Mr. Loudon's works, to which Mrs. Loudon's own talented assistance so justly entitles her. For such a man as Mr. Loudon, after a long life of incessant mental toil for the benefit of mankind, to die so poorly remunerated, is painful to contemplate; especially when we reflect that his embarrassments were occasioned by the immense outlay necessary to produce that valuable and herculean work, the "Arboretum et Fruticetum Britannicum," which must be acknowledged, considering the bodily disadvantages under which for many years Mr. Loudon unfortunately laboured, to be unequalled in the annals of authorship and indefatigable perseverance. To immediately release this distinguished man's family from embarrassment is a debt the horticultural world owe to his memory; his name must ever be associated with the brightest era in Gardening, for to him we are principally indebted for having raised Horticulture from a state of ignorance and empiricism to the rank it now holds amongst other scientific professions. I sincerely hope the purpose for which this meeting is to be held may prove as successful as the most sanguine friends to its laudable object could desire; and I trust that all who take an interest in its furtherance will attend, if possible, and likewise use their personal influence with their friends. It gives me much satisfaction to be enabled to state that a meeting for the same purpose will be held in Edinburgh after the London one, under the kind auspices of Dr. Patrick Neill and other influential gentlemen.—*Joseph Paxton.*

Lemons.—"M. B." forwards a Lemon that was gathered 3d Sept., and the same day put into the box in which it now is (with another which has been taken out); it is now five months since it was closed up. "M. B." preserved two Lemons in the same way for six months, having put them in the 1st of March, 1843, and not opening the box till the 1st of the following September: they were both as perfect as the one sent. [This was a fine specimen, not at all shrivelled, but perfectly plump and sound; and the simple way in which it has been preserved (being buried in fine soil and earth in a small box), is deserving the notice of those who may have more Lemons ripe at one time than they can use.]

Schizopetalon Revili.—This plant has a beautiful appearance in the open border during the summer months. The seed should be sown in the month of April, in pans, in a mixture of peat and loam; then place the pans in a hot-bed, frame, or pit, until the plants are fit for potting off. The seed should be sown very thin, if not, the weaker portion of the plants will rot off, for want of air and room to their stalks, as they grow with their foliage prostrate. As soon as the plants are large enough for potting off, fill a quantity of pots with a mixture of leaf-mould, loam, and sand, then place a plant in each pot, and give a little water. Afterwards remove them into the frame or pit; when they have got established in their pots, they may be removed to a cold frame, or greenhouse. In June they may be placed in the open air, and regularly watered during the summer. Towards the end of October remove them to a frame, to protect them from frost. In May or June following they may be planted out where required. As soon as frost is apprehended, take up the plants, with a ball of earth attached to the roots, repot them, and place them in the greenhouse, or frame, till again required.—*J. McI., Hillsborough.*

Societies.

LINNEAN SOCIETY.

Tuesday, Feb. 6, 1844.—Robert Brown, Esq., in the chair. Professor Agassiz, of Neufchatel, and Dr. Schleiden, of Berlin, were proposed as foreign Fellows of the society. Mr. Winterbottom exhibited specimens of Trichomanes speciosum, which he had gathered in company with Mr. Babington, at Brandon, Mountain Dingle, and Waterville, Inverary, in Ireland; also specimens of Spiranthes gemmipara, which he and Mr. Babington had found in considerable numbers at Castletown, Bearhaven, in Ireland. Mr. Anderson exhibited specimens of Brexia intifolia in blossom. A paper was read from Mr. Curtis, on two species of Hymenopterous insects. The first belonged to the family Tenthredinidæ, or Saw-flies, and constituted a new genus, which Mr. Curtis proposed to call Dielocerus. This insect was from the collection of Lord Gedesloh, and had been taken by Mr. Ellis in the Brazils; hence he called the species D. Ellisii. This insect is chiefly remarkable for its larva forming for themselves a cocoon in pomegranates, a fact that has not hitherto been observed amongst insects. The cocoon was exhibited, was oblong and about the size and form of a Jargonelle Pear. The material consisted of a tunic of woolly substance, well adapted to keep off the influence of water as well as to resist the attacks of the Lepidopterides. In the inside the cocoon consisted of about 30 cells, having a close resemblance to those of the common wasp and bee, but nothing like so great a regularity in form, but about the same size. The second insect described was a species of wasp, which Mr. Curtis proposed to call Vespa brevicornis. This insect built a remarkable nest, which had also been brought from the Brazils by Mr. Ellis. This nest was exhibited, and is about eight inches in length, and 15 inches in circumference. It has a conical form, and is suspended from the branch of a tree by its apex. The texture of the nest is very hard, resembling an earthenware vessel, and very different from that of other wasps. At the base there is a small opening not allowing the passage of more than one insect at a time. The nest had not been opened, and as it was so closely made, it was impossible to ascertain the structure of its interior. Mr. Ross exhibited specimens of optical glasses, with indications of a vegetable growth between them. It was the opinion of Naturalists present that the appearances found on the glass were due to the growth of a fungus belonging to the genus Torula.

IPSWICH CUCUMBER SOCIETY.

"The first brace, exhibited by E. Leathes, Esq., an Amateur, commanded universal admiration; but not entering for the sweepstakes, Mr. Latter won the second prize of the Society and a sweepstakes of 4*l.*,—he exhibited eight brace, from 12 to 17 inches long. Mr. Geo. Mills's were the longest, but in other points did not answer to the Society's standard. The exhibitors and their friends afterwards dined together, and spent a most agreeable evening. Mr. Wild, the secretary, stated that he should never be satisfied till he could produce a competition of ALL the Cucumber growers in England, and would at the next meeting propose "That all winners of First Prizes in England should be allowed to exhibit free of all expense," to a class established for that purpose.

The Judges' description of the PRIZE Specimens exhibited February 8th, 1844.

No.	Names.	Prize.	Sect.	Mode of Growth.	Length.	Form	Size.	Colour.	Neck.	Spine.	Rib.	Bloom	Bloom	General Appearance.
10	* E. Leathes, Esq., Newmarket, near Lavenham, Suffolk.	1st Pr. £ 3 0 0	Brownton Hybrid.	Wild's Improved Fit.	13½ in.	Straight	½ inch.	Dk. Green	Short and Thick.	Dk.	Slight	Very	Perfect	Long and Slender.

Reviews.

The Year-Book of Facts. 8vo. Bogue.

This is, as usual, a rich storehouse of information concerning the discoveries in science during the past year. In addition to its usual contents, the volume now before us has a portrait of Professor Liebig. We have only room for a few extracts.

"*The Lactoscope.*—M. Donné has introduced 'A new instrument designed to indicate the proportion of cream contained in milk,' to which he has given the name of Lactoscope. The principle of the instrument is based on the inherent property of milk, which derives its opacity from the globules of fatty matter it contains, in being more opaque as the cream is more abundant. The construction is so arranged that the degree of opacity may be examined in layers of various thicknesses. The milk is placed between two parallel plates of glass, the distance between which can be varied at pleasure, and the flame of a taper is employed as a test; a graduated circle indicates the thickness of the layer of milk, and a corresponding table of reference gives the amount of cream. The sensibility of the instrument is such as to indicate dilution with one-twentieth the bulk of water. Upwards of ten years since was invented a cream gauge, for the same purpose as M. Donné's Lactoscope: it is a graduated glass tube, and has, we believe, been found very useful."

"*Mastership of Grapes.*—M. Payen has read to the Academy of Sciences, at Paris, the report of the commission on a memoir by M. Cezar Lecaze-Tassin, who sought by direct experiment to solve the question—what influence had the leaves of the Vine in relation to the development and maturity of the Grapes? The following results exhibit an explanation of the difficulty of cultivating the Vine in latitudes where temperature may be suitable, but where the atmosphere is frequently foggy. The total suppression of the leaves prevents the development and the maturity of the Grapes. The partial suppression of these organs in the spring provokes the appearance of axiliary buds, which replace the leaves taken away; later, when the buds can no longer be produced, this suppression arrests the development of the kernels, diminishes the quantity of the flesh, retards the maturity and injures the elaboration of the saccharine principle. Want of evaporation, and privation of the solar rays, enervate the organs of fructification. Superabundance of water, and consequently defective evaporation, in a luminous atmosphere, incites a luxuriant vegetation of leaves, but checks the elaboration of the juices, which remain acid and unsavoury: maturation is not accomplished. Finally, in a warm atmosphere, moist and dull, the leaves may increase greatly; but the juices are insipid, scarce, and the embryo is not formed.—*Lit. Gaz.*"

"*Zinc Milk Vessels Poisonous.*—The following extract will show the danger and the folly of the practice of keeping milk in zinc bowls—a custom which has lately become very prevalent: these articles being sold with the recommendation of a larger quantity of cream being produced, owing to the galvanic action. 'I would scarcely have believed (says L. Elanes, of Berlin) that zinc vessels would again have come into use for alimentary purposes, as Vauquelin, 40 years ago, proved that such were certain, after a short time, to hold a certain quantity of zinc in solution. I have found by experiment that a solution of sugar which had stood only a few hours in the summer in a zinc vessel, contained a considerable amount of zinc salts. It has often been stated that the cream will separate more easily from milk, if the latter be kept for a short time in a zinc vessel. As, however, it is known that milk will turn acid much sooner than a solution of sugar, it is the more to be apprehended that some zinc will be dissolved, and such zinc will be the more noxious, as it is well known that even a small amount of zinc will cause spasmodic vomiting.'—*Pharm. Jour.*"

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

EUONYMUS JAPONICUS. Japan Euonymus. (*Hardy Evergreen Shrub.*) Celastraceæ. Tetr.-Pent.-Hexandria Monogynia.—In all respects this corresponds with the account given by Thunberg, of the Ion Curroggi, or black shore-tree, of the Japanese, even to the sporting into a silver blotched variety, also in our gardens. He says it is in Japan a bush about as high as a man. With us it is not as yet higher than three or four feet, but it has all the appearance of becoming much larger. Although no beauty is to be found in its flowers, this plant is of the same kind of value as the common Laurel, Phyllirea, and Alaternus, being a hardy evergreen shrub, with much the appearance of a small-leaved Orange. It is true that in very severe winters it is liable to be killed to the ground, but so are the Bay, the Ilex, and others; it however springs up again and rapidly forms a nice bush. When older it will probably become more hardy. It is easily increased from cuttings of the half-ripened wood, placed under a hand-glass or in a close frame, and shaded in summer. It flowers in July and August, but has not as yet produced fruit. There are two varieties, one with silver striped, the other with gold-striped leaves; but the latter is very subject to run back to the green-leaved, while the silver striped hardly ever changes. It is called in many places, "Chinese Box," the name it bore when first introduced from Belgium.—*Botanical Register.*

LYCASTE SKINNERI. Mr. Skinner's Lycaste. (*Stove Epiphyte.*) Orchidaceæ. Gynandria Monandria.—This plant is generally called Maxillaria skinneri, but it is now classed by Dr. Lindley among the species of Lycaste. L. Skinneri is happily designated by Mr. Bateman as the *facile princeps* of all known Maxillariæ. "It has at length," says that gentleman, writing in the Miscellany of the "Botanical Register" for 1843, "flowered in the collection of the Rev. John Clowes, with a vigour and beauty that could not be exceeded in its native haunts. The flowers actually measure upwards of six inches across, from the tips of the lateral sepals, while the latter are nearly an inch and a half wide in the broadest part. The colours of the flowers are peculiarly delicate, the sepals being pure white, faintly tinged with crimson at the base; the petals are of a more rosy hue, while the lip is almost covered with spots and streaks of the most brilliant carmine. The column, again, is pure white at the apex, and mottled with crimson spots at the base, while a number of woolly hairs are scattered on its underside. The habit of the plant is stately, and its growth free and vigorous, more nearly resembling Lycaste Deppii, than any other species." To this good description it is unnecessary to add more, than that there appears to be two or three varieties of the plant, differing slightly in the size and colouring of their flowers. The one now described was flowered in the excellent collection of Mrs. Wray, of Oakfield, Cheltenham, and is among the best we have seen. An excellent variety bloomed, moreover, about three months back with F. Cox, Esq., of Stockwell. Mrs. Wray's plant flowered in November last. The species has been brought to this country in great numbers by G. U. Skinner, Esq., after whom Mr. Bateman has named it. Its native place is Guatemala; and Mr. Brewster, the gardener to Mrs. Wray, informs us that Mr. Skinner found it growing on rocky and mossy banks, in very moist places. Mr. Brewster, who has been particularly successful in cultivating it, grows it in an open basket filled with moss and leaf-mould, in a temperature ranging from 55° to 70°. No doubt much of its luxuriance is due to the use of leaf-mould, which is likely to prove a valuable medium for many Orchidaceous plants. It should be kept freely moistened in summer, on account of its vigorous habits; but a cool, dryish atmosphere is indispensable during winter.—*Paxton's Magazine of Botany.*

GARDEN MEMORANDA.

Horticultural Society's Gardens, Chiswick.—Many alterations and improvements have lately taken place here, and others are still in progress. The old unsightly flues in the wooden Vinery have been taken down, and cast-iron tanks put up by Burbidge and Healy in their stead; these are 16 inches wide and 6 deep, with a division along the middle to separate the flow and return. The tanks consist of several boxes, 6 feet long, joined together by hollow screws, and are elevated a little

above the floor of the house by brick supports. The sashes are also of this construction, with small circular openings for evaporation, having lids that can be either shut or opened, as required. The house is about 37 feet long and 12 wide; the boiler, one of Burbidge and Healy's, seems to be a very efficient one; the furnace-doors being made to slide horizontally, can be shut perfectly close, and are not liable to get out of order, as generally happens with those that are hinged. The top of the boiler is a shallow basin, 18 inches in diameter; this is intended to hold water, in order to keep up a moist atmosphere if the boiler be introduced inside; but in this case it was not so situated, and was filled with sand, which being an excellent non-conductor, prevents the heat from escaping. This apparatus has not been yet in use, but it promises to answer admirably; and, running along in the Vinery near the front wall, it occupies little room, and has a neat appearance. The curvilinear Vinery is now also heated by hot water. This has been effected by converting the smoke-flues into hot-water gutters, rendered water-tight by cement, and covered with tiles. The boiler (by Weeks, sen.) which heats this is likewise intended to heat three ranges of pits, each 35 feet long; two of them, for Melons, are already nearly finished, in one of which cement gutters covered with tiles are used, the other is furnished with cast-iron tanks; these are to be cased, both sides and top, with porous earthenware material, made to fit, so as to give out moisture, and prevent the roots from coming in contact with the iron, which would burn and destroy them. The tanks are 8 ins. wide and 5 deep; the flow and return being about 3 ft. apart. These pits being upwards of 12ft. distant from the boiler the pipes between the latter and the troughs are bedded in coal-ashes, about 7 or 8 inches below the surface of the ground. By means of stoppers, each pit separately, or all of them, including the Vinery, may be worked as required. A more efficient means of ventilation has also been afforded for the curvilinear Vinery; this has been effected without disturbing the iron-work or glass, by enlarging the openings at top, so as to communicate with a frame-work covered with zinc, and having vertical shutters in front, turning on pivot-ends so as to open or shut easily up or down, by means of a cord fastened to the upper side of the shutters. The border outside is covered with Croggon's asphalte material, in order to keep the roots of the Vines from being chilled by the snows and cold rains of spring. Having no unsightly appearance, this material is well adapted for Amateurs who grow Vines in greenhouses near or in connection with a sitting-room. The house formerly employed as a Pine-stove has lately undergone great alterations and improvements, and is now an excellent house for Orchidaceæ and other stove-plants. Both back and front walls have been raised five or six courses of bricks higher, in order to admit of a passage being made round the front of the bed. The house is 50 ft. long, and 18 ft. wide, with a bed in the centre for the plants. Hot-water gutters, having a flow and return, covered with tiles, run along the bottom of the bed, the space above them being filled with brick-rubbish, over which the pots sit. These gutters keep up a steady heat in the bed of 80°; they are supplied from an iron cistern, in which the flow-pipe terminates at the further end of the house from the boiler. Between the passage and front wall is a slate shelf 2ft. wide, with an edge 1½ in. deep, for placing plants on. About the middle of the house, against the front wall, is placed a large slate cistern, in which the rain water from the roof is collected. In this, from the pipes passing below it, the water is kept in good condition for watering the plants. Several of these were in bloom. Begonia manicata was here producing a fine panicle of pretty delicate rose-coloured flowers. A small plant of Dendrobium moniliforme was also remarkable for its pretty purple and white blossoms, which contrasted well with the showy Gesnera zebrina that was standing near it. Near this house is a range of pits, forming three sides of a square; these have been recently heated by hot-water gutters by one of Barton and Jarvis's double drum boilers. This boiler answers the purpose of heating very well; but the tanks, being covered with tiles, emit too much moisture during dull weather, in winter, for cuttings and flower-garden plants, with which these pits are filled. The plants in the Orchidaceous house are considerably improved, and have a very healthy appearance; a good specimen of Dendrobium nobile, with several other plants, was coming into bloom. Many specimens are growing on charred blocks, and show, from their fine healthy dark green foliage, that they like their situation, the charcoal no doubt having a beneficial effect upon them. Several Ixoras in the next house were growing in soil mixed freely with superphosphate of lime; this has not been long enough applied to thoroughly prove its effects; but the plants appeared to be in perfect health and doing well. This substance, unlike some of the other artificial manures, is perfectly harmless, and may be used with advantage in the cultivation of most plants. In the curvilinear stove a large plant of Lælia superbiens is throwing up a strong flower-stem about 2½ feet long, and will soon be in bloom. Here was also a plant of Xylophylla latifolia, about 6 feet high, completely covered with small pale yellow flowers; this plant had been potted in June, chiefly in charcoal mixed with peat, and a little loam, which, besides having a beneficial effect on its growth, has dispersed it to bloom freely. There was also in this house a fine specimen of Euphorbia speciosa, fully 5 feet in height and 6 in diameter, producing a multitude of showy blossoms. In front of this stove is a range of pits that were altered some time ago and heated by Gaston and Arnold's horizontal cylinder boiler, which, on account of being set with too small a space for the smoke, chokes up with soot when coals are used either separately or mixed with coke, and does not work well. In the large conservatory, a fine bush of Templetonia glauca, covered with bloom, is very conspicuous, and here Lucculia gratissima, which is usually treated as a stove-plant, is very healthy, and flowering profusely in a temperature from 40° to 50°. In the open grounds at this season there is little novelty to notice, except some rock-work constructed with rustic terraces in a corner of the arboretum, near the large iron tent, which is to be planted with hardy Ferns, for which the situation, being immediately behind a south wall, and shaded in summer by trees, is well adapted.

The Naturalist's Corner.

Remedy of the Citron against Poison.—Athenæus relates a remarkable story of the use of Citrons against poison, which he had from a friend of his, who was governor of Egypt. This governor had condemned two malefactors to death by the bite of serpents. As they were led to execution, a person taking compassion on them gave them a Citron to eat. The consequence of this was, that though they were exposed to the bite of the most venomous serpents, they received no injury. The governor being surprised at this extraordinary event, inquired of the soldier who had guarded them, what they had ate or drank that day; and being informed that they had only eaten a Citron, he ordered that the next day one of them should eat a Citron and the other not. He who had not tasted the Citron died presently after he was bitten; the other remained unhurt.

Ulva palustris.—It is not certain, observes Professor Martyn, what plant is the *Ulva* of the ancients. He himself interprets it in Virgil's Georgics as *Sedge*, which is a general name for large weeds that grow in marshes and near the banks of rivers. Most writers, says the Professor, suppose the *Ulva* to be much like the *Alga*, or *Sea-wrack*, and that they differ chiefly in this: that the *Alga* grows in salt water, and the *Ulva* in fresh. But he goes on to mention one thing as certain—namely, that there is no fresh-water plant which resembles the Sea-wrack; and agrees at the same time with what the ancients have said of their *Ulva*. Cæsalpinus supposes, and not without reason, that the *Ulva* is the same with the *Typha*, which we call *Cat's-tail*, or *Reed-mace*. It is a very common weed in this country, and also in Italy, among stagnant waters; it grows to a considerable height, and bears a head at the top of the stalk, which, when ripe, affords a great deal of down. In the Third Georgic it is called a marshy plant, and in the Eighth Eclogue it is described as growing near a rivulet. In the Second Æneid, Sinon mentions his lying hid amongst the *Ulva*, in a muddy lake. The Cat's-tail grows only where there is mud, and is tall enough to conceal any person. In the Sixth Æneid, again, it is represented as growing by a muddy river's side, and the colour is said to be glaucous, or bluish-green, which agrees also with the Cat's-tail. Ovid makes frequent mention of the *Ulva* as a marshy plant. In the fourth book of his Metamorphoses, a pool is described as being remarkably clear, by the negative quality of not having any *Ulva* in it; in the Sixth Book it is called "delightful to the marshes." We find it mentioned also as a water-plant in the Eighth Book, in which Ovid speaks also of a bed being made of the *Ulva*. This agrees with what Matthiolus tells us, that the poorer people in Italy make their beds of the down of the Cat's-tail instead of feathers; and the same Author informs us that there is hardly a standing water in Italy which does not abound with Cat's-tail.

Miscellaneous.

Remarkable Sport of a Currant-tree.—A Red Currant-tree, which had been planted about 10 years, produced this season, at the top of one of the branches, 5 white berries; and lower, on the same branch, was one half red and half white among others entirely red.—*Revue Horticole.*‖

University of Erlangen.—At the recent jubilee of this University, Robert Brown was elected an Honorary Doctor of Medicine; and the Baron Delessert was made a Doctor of Philosophy.—*Bot. Zeit.*

Preservation of Plant Supports.—In 1840, at the suggestion of the Professor of Chemistry at the Museum, I had the points of a number of stakes of Fir wood done over with Seyssel asphalte. These stakes were placed in a soil constantly moist. At the present time (Sept., 1843), they are still as sound as they were at the first hour. The asphalte was laid on very hot with a brush, the wood having been previously heated. It was laid on to the thickness of 1-12th of an inch, by repeated applications. The last coat was smoothed over with a wooden spatula. The bark should be taken off the lower end of the stakes; and the coating should extend three inches above the surface of the soil.—*M. Neumann, in Revue Horticole for Sept.*, 1843.‖

Effects of Frost on the Roots of the Elm.—According to some experiments respecting the sensibility of the roots of trees exposed above ground to the frost during winter, and replanted in spring, it was found that the Elm was most affected. This fact has been again confirmed by new observations made by M. Pépin, who states that although the temperature was only—5° centigrade, or 9° Fah. below freezing, the effect on these trees was very evident. In the winter of 1842-3, he exposed equally the species of Elm; when about to be planted he found their roots all more or less injured by the frost: they were black; and some were entering into a state of decomposition. The roots were carefully dressed in with the knife, even to the quick, but, notwithstanding, three species died, namely, *U. campestris*, *canadensis*, and *rubra*; the other species are in a languishing condition, although the spring was very favourable for transplanting trees. What is very remarkable, the roots of the Jujube, Pistachio, Pallurus, Adelia, Gleditschia, and other exotic trees, together with some from the south of France, have not been injured by frost, although equally exposed with the Elms.—*Revue Horticole for Sept.*, 1843.‖

The Royal Agricultural and Horticultural Society of Ghent—has fixed its second quinquennial exhibition for Sunday the 10th March next, at which gold and silver medals will be awarded to the most successful competitors. The highest prize is a medal worth 150 francs, or 6*l*. The award of the Judges will be made on the Saturday. At two o'clock on Sunday will be a banquet at which the Judges, winners, and members of the Society, will participate. The exhibition will commence on Sunday at 11 A.M., and close on Wednesday at 5 P.M.

The Weather.—Notwithstanding the cold weather that has now prevailed for some days, we have a specimen of an Ash-tree, almost in leaf, from Gwrych Castle, the seat of J. H. B. Hesketh, Esq., near Abergele, on the coast of North Wales.

Adulteration of Tea.—On Monday, Mr. Warrington read before the Chemical Society an interesting paper on the Adulteration of Tea, which brought to light some very startling facts. The Author having lately had occasion to examine some samples of Green Tea, discovered that it had been coloured with Prussian blue. This led him to examine a number of samples of genuine Chinese Green Tea, the result of which showed that the Tea in China is frequently thus adulterated: Tea of inferior quality and bad colour being powdered over with Kaolin and Prussian blue, so as to make it resemble the finest Green Tea. Mr. W. has likewise detected, by the aid of the microscope, a number of other leaves mixed with those of the Tea plant, in samples of Tea from China.

A New Berry.—A few evenings since, at a small party in Gardiners' Lane, where, of course, not one of the company had any knowledge of Horticulture, the mention of the Service Berry (or Sorb) gave rise to a discussion as to what sort of berry it was. One person thought it was either the lip or haw; another that it was a species of "Cranberry;" a third that it grew on the Elder tree—nobody appeared to have had any acquaintance with the fruit; till at last an old half-pay officer guessed—and was held to have solved the riddle—that it was a sort of berry you got in the Service, commonly called a bullet.—*Hood's Magazine.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

As the season advances, give more air to the houses. See that suitable composts are ready under cover for potting and sowing seeds. Some of the hard-wooded plants may now be propagated by cuttings, where a gentle bottom-heat can be kept up. As charcoal is now allowed by all to be of use to plants, endeavour to get a supply of it at hand for mixing with the soil before the potting season arrives. Do not increase the temperature yet, and take care that all the plants are clean, and free from insects.

Conservatory.—The early-forced bulbs will now be out of bloom, and should be removed to some sheltered place, in order to ripen their foliage, where frost is excluded, and other plants may be introduced from the forcing-houses. Hibiscus, Clerodendrons, Justicias, and other half-stove plants which flower in the conservatory, may be pruned, and some of them placed in a higher temperature; but they should not be potted until they begin to grow freely. A few Nerriums and Hydrangeas may be also forced into early growth for this house. A gentle heat would now benefit the Chinese Azaleas for early flowering.

Greenhouse.—Continue to give as much air to this house daily as the state of the weather will admit of, and see that all the plants are watered regularly; the great object is to keep these plants from growing early.

Forcing-pits.—Continue to introduce fresh supplies of plants as the former ones are removed to the conservatory: also other plants from which you wish to obtain an early crop of cuttings, such as Salvia splendens, to come in early in the autumn. Common plants that do not promise much bloom should be at once discarded to make room for others; failures of this nature always occur more or less in early forcing.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department

After the late frost and snow the ground will not be in a working state for some days to come. The directions of last week may be attended to in the shrubberies, and in the flower-garden Roses may be pruned and deciduous climbers regulated and tied or nailed properly. I am not an advocate for close spurring, but prefer cutting out the old wood and replacing it by young shoots every season.

Pits and Frames.—Here, if the number of plants required for bedding out is considerable, there will be plenty of employment for all hands. The whole of the autumn-propagated plants must be potted off without delay, so as to get them well rooted, and turned out into sand in temporary pits by the 1st of April, and so as to set the pots at liberty for a second lot of plants, which should now be coming forward in the propagating frame. It is of no use to plant Verbenas, &c. for beds a foot or two apart, as the experience of the last three summers proves that unless we plant en masse at once, the flower-garden will present only sulky borders until August or September; therefore, where we wanted one plant in past years we shall in future require four or five, and consequently a corresponding provision must be made. Hydrangeas introduced into the forcing-house in January will now require to have their side shoots removed, to give strength to the leader. These shoots must be used for propagating, to provide plants for another season. Sweet Peas, if wanted to bloom early, must be sown in pots in heat, for transplanting; indeed, a general assortment of the best annuals must now be sown in pots for the spring and early summer decoration of the flower-garden.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Should frost and snow continue, it will leave the Florist little to do out of doors.

Tulips ought to be out of harm's way.

Pinks, if defended in the manner recommended in a previous Calendar, may bid defiance to hares and rabbits.

Ranunculus-beds will be all the better for frost and snow. The final arrangement of the roots for planting may now be made, keeping all flat-crowned ones for the side-bud.

Auriculas, though occasionally covered, as the trusses are rising in the hearts, ought to have air whenever practicable—withdrawing or tilting the frame-lights in the middle of the day, if only for half an hour.

Carnations may remain *in statu quo*. My own frames have had a current of air passing under them during the whole of the frost

shading being closed at top to prevent the ingress of snow or rain. The Gardener may employ his leisure time in manufacturing and furnishing Dahlia shades, making small three-cornered paper bags for ripening off Tulips and Ranunculus roots next season, painting or otherwise marking zinc labels, and attaching metallic wire to them for Dahlias, Roses, &c. &c.

Turn compost heaps whenever the tops are frozen.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—Look frequently to the state of the soil in those pots situated near the pipes or flues, and apply the waterings only in such quantities as to prevent an injurious state of dryness, and sprinkle the tan whenever it becomes too dry. Endeavour rather to keep the atmosphere of the fruiting-pit constantly in a genial moist state, than to have it very full of steam at one time and dry at another. Choose mild open weather for shifting the succulent plants. Fines suffer much from being taken out of the pits in cold or windy weather.

Vinery.—After the Grapes have been set six or eight days, commence thinning the bunches; in the performance of which, use something with a smooth surface to steady the bunch, in preference to handling them. I need hardly say that the outside berries, if equally promising, should be saved See that the bunches is not crowded, or too close to the glass, and do not let the Vines exhaust their strength in producing long laterals.

French House.—In the house started in November, the thinning of the shoots should now be finished. Reserve those side-shoots produced at the base of last year's wood, and tie them in when a foot inches in length. If the fruit has set thick upon the trees, thin them, leaving the most promising fruit that are well situated for swelling. The last few days have been unusually favourable for the Peaches; and from the progress they have made, we can afford to use them more gently with regard to fire heat, should very cold nights ensue. Nothing is more injurious to them than over-heating the pipes or flues.

Fig-house.—The glass being usually kept upon the Fig house during the winter, the soil will be dry for a considerable depth. Previous to watering the border, spread about three inches of chopped turf over it. The turf will keep the water from running to the lowest point, and will invigorate the plants. Let the water be in a tepid state.

Cherry-house.—The Cherries that are set should have the blossoms removed by means of the syringe, using a fine rose. Admit air daily, if possible, and keep the atmosphere in a soft genial state. No insects should be allowed to exist here.

Strawberries.—The most forward plants will now demand more attention. Remove all runners as they appear, and sprinkle the plants twice a day in fine weather.

Melons.—When the plants are in the rough leaf, it is time to prepare for turning them out. If the frame culture is to be followed, lay thick turves round the inside against the row of faggots on which the frame rests (see last week's Calendar), pressing it close, so as to prevent rank steam from entering. Lay, also, a layer of turves on the dung and leaves, then raise a mound of well-decayed turfy-loam under the centre of each light, within a foot of the glass. Apply a lining of previously fermented dung to raise a heat of 60° or 70°.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Fruit and Store Room.—Examine all fruit and roots, protect them from frost, and see that seeds are not injured by damp.

Cucumbers.—The materials will now be ready for forming a bed. If the matter consists chiefly of dung, excellent directions will be found in the forcing Calendar of last week, as recommended for the Melon. If the greater part of the material consist of leaves, many faggots will not be necessary; but drain-tiles passing through the bed as recommended for Asparagus, &c., will answer better. In such a case the bed will require to be rather better than 3ft. in depth at this season, and if there is a sufficiency of material to make it long and wide enough to admit a space of 18 ins. round the outside of the frame, and if the sides and ends of the bed are defended by wattled hurdles, a steady heat will be generated, and linings will not be seen wanted.

Rhubarb and Rhubarb.—If these were protected as recommended in the beginning of the year, and are now covered with pots or boxes, very little heat will be necessary to bring them forward.

Carrots, Radishes, Asparagus, Potatoes, Sea-kale, and Cauliflower, in pits and frames, will have required considerable protection. Where litter is scarce, it should be frequently shaken up in keen frosty weather.

All ground Operations having been suspended for a short time, a good opportunity has been furnished for forwarding in-door work, such as tying mats, preparing stakes, cutting labels, making straw covers, mending nets, cutting shreds, &c. It is miserable policy to keep men out-of-doors in unfavourable weather.—*R. F.*

VI.—AGRICULTURE.

Odd Weeds.—Continue the works, where not finished, as formerly directed, such as felling timber-trees, relieving young plants and trees from the overgrowth of others, clearing out drains and ditches, repairing fences, and planting young trees where there are vacancies.

Coppice.—The directions given last month should be made use of at all convenient times, until the works for the season are completed; and they should be skilfully and properly executed, particularly with respect to the training, and regulating those for poles, rods, &c. likely to be saleable, and keeping all other useless stuff down, so as not to injure them.

Young Plantations.—Bear in mind what has been previously recommended, viz., the importance of training and thinning of young plantations. About the second or third year after a plan tation has been planted, begin to train the young trees, as many kinds, such as Oak and Spanish Chesnuts, often get stunted and bushy-headed, and are sometimes years before they make a start to grow. In consequence of this, the less valuable trees grab the lead, overtop, and smother them, arising from not cutting some shoots clean out and shortening others, so as to make the tree form a good leader. Some of the very strongest lower-side branches, if pruning has been neglected, should also be taken off.

Hedge Rows.—The directions given last week should be kept in mind and followed up until the work is completed for the season.

Nursery Work.—As the weather is unfit for planting, or sowing seeds of forest-trees, shrubs, &c. for underwood, trenching, digging, and preparing the ground for them should be forwarded when the weather permits. Young trees planted out in rows should be trained, as they often get stunted and bushy-headed, similar to what I have just described in young plantations, and the same process of training recommended there, after the second or third year should also be adopted and followed up here. I much fear the means of accelerating the growth of timber and coppice wood will make little progress until there is an Arboricultural Society established, with plantations for the purpose of experiment in order to show the effects of training, &c.—*W. B.*

State of the Weather near London for the week ending Feb 6, 1841, as observed at the Horticultural Garden, Chiswick.

Feb.	Mean's Barometer		Range of Temperature			Wind	Rain.
	At 9.	Mean.	Min.	Max	Mean.

The highest temperature during the above period occurred on the 16th, 1841, and 16th and 17th, 1827—thermometer 55°, and the lowest on the 15th, 1838—thermometer 16°.

Notices to Correspondents.

MR. PAXTON'S COTTAGER'S CALENDAR.—At the earnest solicitation of many of our Subscribers, we have determined on again reprinting Mr. Paxton's "Cottager's Calendar," in the form of a small volume, for general distribution, price 3*d.* each copy. It may be ordered of all booksellers. Gentlemen wishing to *distribute copies* among their cottage tenantry, may have them *delivered in any part of London*, by remitting a post office order to this office, at the rate of 25*s.* for every 25 copies.

OUR CORRESPONDENTS will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

COMMUNICATIONS from the following CORRESPONDENTS are in type, and are only waiting till room can be found for them—*O., Vitis, W Billington, R. Errington, J. L. Snow, G. Thompson, J Wighton A Practical Man, Peter Mackenzie, Nemo, J M'I., A Friend to Floriculture, A Bee Preserver, C. A Lloyd, Philo Sylva, A. F., R. P. N., Herbert, Sussex, R. Dixon,* and *I. W. K.*

BLACKENING GARDEN WALLS.—*D. M. C.*—We retain our opinion. The experiment was fairly tried in the garden of the Horticultural Society, some years since, and the blackened walls still remain there, with the trees upon them. No advantage has been discovered. If you have any *facts* in favour of the practice, and will give us your address, we will, however, publish them with pleasure

CACTI.—*M. D.*—Possibly your fruit is ripe; if so, it will be soft and tender, although green. Probably, however, it wants more heat. In any case, you must wait till it shows signs of some change of colour before you gather it. When mature, rub it in water till it is freed from the pulp, and sow it thinly on the surface of any soil kept rather dry, and placed in a Cucumber-bed. Young plants will soon appear, and grow rapidly, if kept warm and damp, and fully exposed to light, but not to wet.

COPPICE.—*A C. P.*—If you have any considerable quantity of planting to do, you will easily ascertain the lowest price of trees per 1000 by advertising for tenders The best size for planting is from 1½ to 2 feet high. We will answer your question as to distance next week.

CORRESPONDENTS.—*P.*—Much obliged, but the article does not suit our columns. No man ought to write on landscape-gardening who has not experienced the advantage of an education at least good enough to enable him to write good English. You seem to mistake groundwork for landscape-gardening.

FERNS.—*Arran.*—Remove ferns now, but not much later.

FIRE.—*Clericus*—Very small quantities of nitrate of soda will set these plants growing, but it must be applied cautiously The best way is to water them with it three or four times when they are beginning to grow. One ounce in two or three gallons of water is plenty. Mind, however, that your nitrate is not adulterated with common salt

GREENHOUSE PLANTS.—*Omega*—Cut them down at any time when at rest, unless hard-wooded, and then at the time when their buds are just beginning to swell. Dissolve half an ounce of nitrate of soda in a gallon of water Potter's guano and the super phosphate of lime are both unrivalled as manures.

HEATING.—*H. I.*—Very good tanks may be made of slate, even as large as you want. Others are made of iron, and answer perfectly You will find persons to supply either by consulting our advertising columns——*S M B*—No doubt your heat is all absorbed by the material that rests on the tank If you have not left the sides of the tank uncovered, which you should have done next the outside walls of your house, you must now make chimneys from the surface of the tank, opening into the house Common chimney pots will do——*G L H.*—Open brick gutters are not used at the Horticultural Garden.——*M. D.*—You must get an iron pipe that has been cast close at one end. It is to be had at all the places where iron pipes are sold

ISABELIA—*A Subscriber.*—We recommend you to cut off the infested excrescences, which contain the embryo aphides, to scrape away the earth from the base of the trunks, where, probably, many more are lodged; and before the mild weather arrives to brush and wash the trunks well with either gas-water, lime and water, soot and oil, or train oil alone no part of an infested tree must escape, viz., of the trunk or the larger branches. The operation must be performed before the buds burst, and the trees ought to be carefully looked over occasionally in the spring and autumn, when the washing must be repeated if there be the least symptom of a cottony nature. *R.*

IVY.—*C. Bt.*—The little stem-roots of the Ivy appear to serve a double purpose, that of holding branches to the body over which they creep, and of feeding them. The latter, however, takes place in only a small degree; most likely because the bodies to which they are attached are incapable of yielding much food We cannot, however, entertain a doubt that they are true roots in an abortive state. Whether or not they will extend and grow like true roots when placed in the earth, or whether they are paralysed organs, we do not certainly know. But the mischief done by Ivy to the mud walls of cottages and to ruinous brickwork, which is overset by the roots of the branches, renders the former the more probable.

LAWNS.—*W. B*—These may be either turfed now or sown with grass-seeds in March or beginning of April

NAMES OF PLANTS.—*A Reader.*—Maxillaria punctata.——*W. Gardner.*—Maxillaria Barringtoniæ——*M.*—Dillwynia ericifolia——*Amateur*—We do not know such a plant as the Pine Myrtle, nor do we recognise its seeds. No doubt, however, you may raise it in a hotbed and preserve it afterwards as a greenhouse plant by very ordinary management

PEARS.—*Non sum qualis Eram.*—Such will also apply to the Winter Bon Chrétien Pear. The Glout Morceau is far preferable for your lofty gable facing the south; if your nurseryman has it not, he certainly can procure it.

PERENNIAL FLOWER-SEEDS.—*A Reader.*—These may be sown in March, in pots or shallow pans, in a soil composed of peat-loam and sand. They should be covered deep or shallow, according as the seeds are large or small; the larger ones should seldom be deeper than half-an-inch, while those that are small may be only lightly covered. If a slight bottom-heat can be afforded them, it will make them germinate more rapidly.

PLANTS.—*C. B—l.*—The following are 24 hardy greenhouse plants, of dwarf habit, that bloom freely, which are suitable for planting in a bed in the house, viz:—Acacia armata, Choisya ternata, Correa speciosa, Cytisus racemosus, Daphne indica, Diosma ericoides, Epacris grandiflora, Erica hyemalis, Eriostemon buxifolium, Genista canariensis, Hedychium coronarium, Hoya carnosa, Jasminum revolutum, Leschenaultia formosa, Myrtus communis, Pittosporum Tobira, Polygala oppositifolia, Sparmannia africana, Tetratheca ericifolia, and Westringia rosmarinifolia.

RHODODENDRONS.—*H. Weeks.*—The following are tolerably hardy, and may be grown either out of doors or in a greenhouse; but when grown in the latter, the flowers come much more perfect; they are free-blooming, and may be easily procured by their names. Ponticum, scarlet; Lowii, pale straw, with brown; tigrinum, pale rose, with dark brown; Nobleanum, dark red; splendidum (Cunningham's), white; atrosanguineum, scarlet; multimaculatum, pale rose, spotted; arboreum roseum, bright rose; Victoria, deep red; venustum, pink; augustum, pale flesh, spotted; pulcherrimum, scarlet; grandiflorum (Cunningham's), pale flesh; macranthum, rose; Knightii, scarlet, and Carnarvonianum, bright rose.

ROSES.—*C. B——t.*—The following are 24 Tea-scented or other Roses which are suitable for growing in a Greenhouse, being planted out in the beds, viz.:—Emilie Courtier, rose large; Barbot, yellow edged with pink; Caroline, blush with pink centre; Comte de Paris, blush; Elise Sauvage, pale orange; Julie Mansais, white; Adam, bright rose; Bouquet de Flore, carmine; Ceres, rose; Madame Aude, rosy pink; Prosperine crimson; Hamon, pink and buff; Armosa, light pink; Theodore, pale yellow; Calimene, blush; Queen of Bourbons, buff; Gombault, pink with buff centre; Augustine Lelieur, deep rose; Duchesse de Mecklenburg, straw-coloured, very large; Devonensis, yellow; Aurore pale buff; Hardy, bright rose; Belle Helene, blush; and Jaune panaché, pale yellow and rose. The reason why many Roses of the above kinds do not fully expand their flowers, is chiefly owing to want of heat.

STAR JELLY.—*J. J.*—Your question was answered at p. 56 in the Number for 27th Jan.

TIMBER.—*E. H. Lloyd.*—We will make inquiries.

TULIPS.—*Inexperiens.*—The plan you mention for the protection of a Tulip bed is, perhaps, the nearest to our view of the subject, but a temporary protection for winter, is, we think, preferable to any that we have hitherto seen designed to answer the purpose of both, especially for a bed of moderate size. Drive a strong stake, 18 in. or 2 feet long, close to the inner edge of the frame board (which inclosures your bed) at each end, and a similar parallel one in the centre of the bed. Then nail a strong lath, or 1½ inch deal, upon the three stakes, extending the required length; procure strong wooden hoops, and drive one at each end opposite each stake, fixing each in the centre to the top of the stake, placing a small wedge at the base of each to admit a packing needle between each hoop and the board. Each end of the bed may then be faced outwardly with a portion of garden-mat sown round the edge of the hoop—thus each end will appear a neat fixture for the winter season. According to the distance of the hoops, if wide, slender cord may be run continuously round them to give additional firmness. The remaining mats should then be prepared by sowing two or four together, edge to edge, and thus placed in their intended position over the hoops; when the required number is thus placed, a strong strip of cloth listing should be fitted to the strip of wood along the centre, outwardly, and the mats nailed to the latter. Being fixed to the centre, they are rendered equally secure by (their ends resting upon the broad wooden frame, or otherwise upon the ground) a strong iron rod or wooden wedge resting upon them the entire length The covering can thus be rolled back to the centre on either side without inconvenience; or the latter, which too often attends a loose covering. Thus far for the winter. For the summer protection, bent iron hoops are perhaps the best, being portable. The boarded sides should be sufficiently strong to admit each hoop to be screwed on by an iron plate at the base The side and centre rods should be so massy as to give firmness to the whole structure. They might either pass through holes or rest upon hooks; they may also serve for effect as well as for use. The covering, if of strong material, may be tied to the rods. Such a plan, we think, (where means will admit,) is the most economical, because the most lasting.—*W. W.*

VERBENAS.—*Arran.*—If the seed is sown on a hot-bed in March, and planted out in May, they will flower in the autumn.

MISCELLANEOUS.—*Plymouth.*—Your letter having inadvertently was not answered last week. We would help you with pleasure if we could alter our arrangements, but that is impossible. Where men cannot afford to purchase the *Gardeners' Chronicle*, and wish to do so, it is to be hoped that their masters will procure it for them, especially if, for the sake of his Agriculture, it now passes, as you say, from the house to the farm, and not to the garden. However, these are private arrangements with which we cannot interfere.——*P. H. B.*—As far as we at present know, Whitney's Composition is the best that has been prepared for rendering calico transparent; but we do not know how far its durability can be relied upon, nor are we sure how far it is economical. You can, however, easily get a bottle and try the experiment. We hear a good account of a composition described at p. 139, 1843. You will find Mr. Whitney's agents named in our advertising columns.——*R. E.*—We never heard of the Carolina Gurken Cucumber. The prickly fruit sometimes seen in pickles, is the young of Cucumis prophetarum, but it is not a good thing.——*Fidfager.* Sand is used in gardening merely as a means of mechanically improving soil; and therefore any well-washed *fine* sand that is not coloured by iron will do. Your question about your cellars is one for a builder. We should suppose that a good bed of concrete, well made, would be the most advisable substance to employ, provided the arches will bear its weight, and in that case earth may be laid on it, and fruit-trees can be planted thereon.——*R J.*—It is impossible to answer your question. One family of 25 persons will waste or consume twice as much as another, and one garden will be twice as productive as another The common rule of ¼ acre for four persons exclusive of servants is not enough. Land is of little value in the country, and it is better to have too much than too little. The right way to determine a point of this sort, is to ascertain how many Cucumbers, Peas, Beans, Lettuces, and so on, the family is expected to consume, and then to provide land accordingly. Always grow Potatoes in the field.——*Laddie.*—You are right in having broken up the bottom of your pent-beds, and wrong in having made them 4ft. deep. A foot and-a-half of soil is sufficient for American Plants. If the soil is likely to burn or dry up, give it a good dressing of cowdung.——*Olim.*—Plant Dianthus deltoideus or cæsius. We will try and find a receipt for fumigation against next week.——*Tyro.*—The South Carolina Potato is the tuber of Convolvulus Batatas, and can only be grown in this country in a warm Cucumber frame. It takes up a good deal of room. Plant it without clothing.——*E. T.*—Cut your Hollies down about half way, as soon as you see them begin to swell their buds in the spring.——*A Subscriber.*—We regret to say we know no more about the yeast than we have published.——*M. G.*—No doubt flowers will travel well in tin boxes for a fortnight or so: but we call that space of time "a few days." The answer to which your remarks apply was to a complaint that flowers could not be preserved for many months!——*M. W. C. L. D.*—We are unable to find room for your remarks, which can do no good, for who does not know the importance of employing that time? Want of money, or want of inclination, are the obstacles, and a panegyric on *Lord B.*, whom we know to deserve all you say, will not remove them.——*Arran.*—Your Amaryllis longifolia wants heat and water when growing. It is half deciduous.——*D. S. W.*—A paper on Gladioli will be published very soon.——*X.*—Get an engagement in some French garden before you start. If you do not you will have to return. But you are better at home; for what can an English gardener learn of the French, except in trifles? English gardeners are as superior to most French as she is to her.——*A. B.*—The Newspaper cannot be sent by post unless the stamp happens to be on that part of it, which is without the case.——*J. Sterling.*—We do not know.——*P. T.*—We believe near Manchester.——*S. P.*—We cannot recommend Tradescantia. Chinese Primroses may be had of most nurserymen in Manchester.

**** As usual, many communications have been received during the week for answering this week.

ALTERATION of the TIME of holding MONMOUTH SPRING FAIR.—The inconveniences of holding the Spring Fair on the 15th of April having been felt, in consequence of several other Fairs in the neighbourhood being held about the same time, the subject has been taken into consideration, and a representation made to the Mayor and Town-Council of the Borough, who have decided that, in future, the MONMOUTH SPRING FAIR shall be holden on the Wednesday next after the 15th of February.

Notice is hereby given, that the MONMOUTH SPRING FAIR will this Year and in Future be Holden on the WEDNESDAY Next, after the 15th of FEBRUARY.

By Order of the Town-Council.

Dated this 27th day Jan., 1844.

The Agricultural Gazette.

SATURDAY, FEBRUARY 10, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Feb. 14 . Agricultural Society of England.
Thursday, Feb. 15 . Agric. Imp. Society of Ireland.

Wednesday, Feb. 21 . Agricultural Society of England.
Thursday, Feb. 22 . Agric. Imp. Society of Ireland.

THE economy of any practice is to be ascertained by a comparison of its cost with the nature and quantity of its result. This is sufficiently obvious. The actual sum of money spent may be large, but it may be *profitably* spent for all that; and if so, though a heavy, it must be considered an economical, outlay.

In estimating the economy of certain branches of farm management one is apt to overlook this, and to condemn an expensive outlay before ascertaining the returns from it. This remark is, at any rate, applicable to the question we often hear discussed at Farmers' Clubs—WHAT IS THE BEST WAY OF KEEPING FARM-HORSES? In attempting to answer this question it is certainly not right to keep one's eye resting only on the cost incurred, that of food—oats, hay, roots—and that of attendance, &c.; we ought, indeed, to look at the sum to which these amount in a given time, but only in order to compare it with the quantity of work which has been accomplished by means of that outlay within that time. If we wish to ascertain whether our plan of keeping farm-horses is economical, we must inquire, not how many bushels of oats are eaten per week, but how much per acre, over the extent ploughed in one week, does the weekly expense amount to. If on any number of farms, of similar soils, which are cultivated alike, the management of the farm-horses be different, then that mode is best the expense of which, whatever it amounts to *per horse*, is least *per acre*. This is the test to which the various ways of keeping farm-horses must be brought.

We propose to consider this important subject at considerable length. It is believed that the expenses connected with it are greater than many farmers think. Indeed, notable differences, which we shall hereafter notice, have occurred among members of certain farmers' clubs, in their estimates of the sum to which they amount per acre. Our present object, however, is to determine the suitableness of the test to which we have referred. When on two farms of similar soils we compare the sums per acre to which the expense of horse-keep on those farms amount, we must remember that it is only in cases where *the cultivation is similar*, that these sums are to be considered as such a test; and not only must the cultivation be similar—not only must the work to be done be the same—but the machines employed in doing it must be similar; for it is evident that two farmers who adopt the same management in their stables, may differ much in their expenses there, if the one uses on his farm cumbrous ploughs and heavy waggons, while the other employs light ploughs and carts; for the former will require more horses to work these implements than the latter.

The importance of good machines on a farm in diminishing various items of expenditure, that of horse-keep among others, will be considered in the course of our articles on Agricultural Mechanics; we only refer to it now, because, before we can admit evidence on our present subject, we must consider to what extent it may be influenced in this way.

The two classes of implements we intend to take up are the cart, waggon, &c., and the plough in its various forms. With regard to the former, the following is extracted from Mr. Pusey's article on Lincolnshire Farming in the English Agricultural Society's Journal.

"*Relative Use of Carts and Waggons.*—The Lincolnshire waggons are very ponderous masses of timber. In the north, light one-horse carts only are used; and here, as the question of carts or waggons is an important one, I will mention an experiment lately made at my request by three Berkshire farmers living near Farringdon. Mr. Edmunds, who has lately introduced one-horse carts, and Mr. Druces, who employs the light Berkshire waggon, agreed to compare the quantity of Wheat carried by them from two fields of similar crop, along the same kind of road, to their homesteads. The result appears in the following table:—

	Driving lads.	Time. H. M.	Distance in Furlongs.	Horses.	Acres of Wheat cleared.
Mr. Druces' 3 waggons	3	4 30	8	7	5
Mr. Edmunds' 4 carts	3	4 0	8	4	5

* This crop carried with waggons was a little thinner upon the land than the other, but not so much as to make much difference in the trial. It was necessary, also, to try the one-horse system in the other branch of farm-carriage, the carting of dung. This was done by Mr. Harris, of Higton. One day he led the dung with his own three-horse carts; the next day he led it to the same field with the one-horse carts of Mr. Edmunds. The strength employed was as follows:—

	Carts.	Driving lads.	Horses.
Three-horse carts	4	3	10
One-horse-carts	5	4	5

"Though the horses on the first day doubled those on the second in number, Mr. Harris carried nearly or quite as much dung on the second day as on the first. These two trials seem decisive in favour of one-horse carts, which are used not in the north alone, but in Bedfordshire and neighbouring districts; and as a cart with a movable harvest-rail may be bought for 13*l*., I have now no longer any doubt that, unless on very deep land, if a farmer will part with all his waggons and heavy dung-carts, buying a complete set of light one-horse carts in their room, he will be quickly repaid by the large immediate saving in horse-keep."

Here we see that it takes twice the number of horses to perform the same work with waggons as with carts. Obviously, the total expense of horse-keep incurred by a Berkshire farmer who uses waggons, might be much greater than that incurred by a Scotch farmer occupying the same number of acres of a similar soil, who employs carts, without there being necessarily greater economy in the stables of the latter; and the importance thus appears of considering these points before receiving evidence upon the various ways of keeping farm-horses.

But this difference not only exists between carts and waggons,—almost as much appears in the trials which have been made between one-horse and three-horse carts. Thus, an article by the late T. J. L. Baker, Esq., in the 1st vol. of the English Agricultural Society's Journal contains the following passage:

"Two heaps of stone, of 32 tons each, were landed from a barge; they were to be taken to the same place, about a mile and a quarter off. A farmer began the first with two large carts and three horses, one cart was being loaded while the other was moving, and the horses were taken off and put on at every load. Finding that he could not do it in the day, he gave over at the end of about six hours, and set to again the next morning. * * * Their work was completed at 11 loads (which of course is nearly three tons to each load, or one ton to each horse), in nine hours and fifty minutes. I began the other heap with three small one-horse carts, and completed it in one day at 21 loads (being nearly a ton and a half to each horse), in six hours and one minute; which was a saving of about three hours and a quarter on nine hours and fifty minutes, or rather more than one third. In this I had three decided advantages—first, the saving of time by trotting back; secondly, the rest that each of my horses got in his turn while his cart was being loaded; and thirdly, the ease with which my carts were loaded in consequence of being lower."

From this account we may infer that a great saving in horse-keep was effected by Mr. Baker by the use of one-horse carts, because fewer horses were required to do the same work in the same time than were needed by the neighbouring farmer with his three-horse carts. It should be stated, that there was some difference here in the breed of horses employed, but that could not account for all the difference in the work performed by them.

Guided by these two cases, we shall be prepared, at a future opportunity, to look somewhat narrowly into the evidence on the subject of *true economy in horse-keep*. Before doing this, however, we have to consider in a similar way the bearing upon this subject, of the variety which exists in the form of the plough. This we hope to take up in our next *Gazette*.

ON THE AGRICULTURAL VALUE OF LAND.

(Continued from page 74.)

3. The way in which the nature of the crops cultivated, and the mode in which they are made to succeed one another, influences the fertility of the soil, is a point which has been much discussed; that it does possess this influence is very evident, from the wretchedly poor state in which some farms are to be seen on which no attention is paid to it, Corn crops being taken off the same land during many successive years; and from the good state of cultivation, on the other hand, to be seen on farms, where a proper rotation of crops is adopted. It is, indeed, an acknowledged fact, that a crop of any kind will exhaust the land it is raised on, and, that if taken off the same land for many successive years, it will, at length, tire it out altogether. Some, however, possess this property in a greater degree than others. Seed-bearing crops, for instance, exhaust the land more than green crops, and a fact arises from this, which seems to have been forgotten by some farmers, namely, that if weeds be allowed to seed, the farmer suffers, not only by their increase in the following years, for "one year's seeding gives seven years' weeding," but also by the exhaustion of his land which they occasion.

It is also an acknowledged fact, that while, generally speaking, Corn crops thrive after green crops, each Corn crop has its particular green crop, after which it thrives best: thus, Barley succeeds Turnips, Oats succeed Grass, and Wheat, Potatoes or Beans; and 1, Wheat; 2, Turnips; 3, Barley; 4, Seeds; 5, Oats; 6, Potatoes, constitute a very good six years' rotation. De Candolle's excrementitious theory was framed to account for this curious preference, which certain crops have for the land off which certain other crops had just been raised. It is supposed that plants exuded at their roots those portions of the descending sap which were not fitted for their own growth, and that, while this excrementitious matter was poison to *them*, it was nourishing food for another class of plants: hence the propriety of making the one kind of plant succeed the other. Another theory supposes that each class of plants, taking from the soil one particular substance necessary for its growth, will die after having at the end of a course of years thoroughly exhausted the soil of that substance; but that for the growth of another class of plants which does not require that substance, the soil is as well adapted as ever. Neither of these theories explain the fact which often occurs, that land, after a course of cross-cropping with only one kind of plant, as the Teasel or Wheat, often becomes so worn out, that it will not yield a good crop of any other plant whatever. This, and many other objections, depending chiefly on the minuteness of the experiments brought forward in proof of either theory, have been urged by practical men against them; and it has been stated that the advantage of a rotation of crops is owing more to differences in the nature and in the cultivation of the crops which succeed each other than to any alleged habit of plants generally,—the account of which depends for its truth on the accuracy of a series of the most delicate experiments. Thus, during the growth of the Wheat crop, the land receives one kind of cultivation, and favours the growth of one kind of weeds; during that of the Turnip crop, the land receives another kind of cultivation, and thus another class of weeds will spring up, if any are allowed to appear. The propriety, then, of alternating these crops is evident. Whether, however, the explanation of the necessity of a rotation of crop be successful or not, that such a necessity exists is established; and the farmer, with reason, acts upon the fact at once, and does not wait till a sufficient reason be given for it.

It has been seen, then, that the fertility of land depends on its mineral composition and on its cultivation. It has been seen that, under the first, the soil may be improved by drainage and by the admixture of mineral substances, any alteration of this kind which it undergoes being permanent; that under the second it may be improved by a proper attention to the management and application of manures—to the looseness and depth of the soil—to the adoption of a suitable rotation of crops; and that any alteration produced by these means is not permanent, but that any departure from the established rules of good cultivation is followed by an immediate decrease of the fertility of the land.

From what has been said it will appear that a knowledge of many of the sciences may be made available by the Agriculturist in the improvement of his land. Chemistry will point out to him where its fault lies, and Geology will often show him where to look for its remedy. Both, if he make use of them, will assist in improving his practice; and in all his experiments, by explaining to him the success of this or the failure of that, will render his business a source of much pleasure as well as profit. Experience, indeed, may, in the end, lead to the same results, and teach the same lessons as a knowledge of these sciences; but the lessons of the one are but imperfectly learned at the end of a long series of years, during which they have to contend with prejudice and custom, and everything tending to subvert or distort the truth; while those taught by the others are learned, and may be made use of at once.—*M. S.*

ON THE WEEDS INFESTING FLAX FIELDS.

As it seems probable that the culture of Flax will be considerably extended in this country within the next few years, it is desirable that attention should be drawn to the prevalence of certain weeds in that crop. Several weeds of a large size are constantly found amongst Flax, which, as they flower sooner than the time for pulling the Flax, may easily be removed by the hand; and as their seeds are introduced into the soil, intermixed with the seeds of the crop, it is of much consequence that the plant should be removed from such crops of Flax as are intended to afford seed for future cultivation.

There is, however, a weed of a far more destructive character, which it is much less easy to destroy, since it can scarcely be removed by hand without very great injury to the crop; and as, at the same time, it is of a very destructive character, it has long appeared to me to be deserving of considerable attention. Accordingly, I have endeavoured, in different ways, to call the attention of Flax cultivators to it.

The weed to which I refer is the Flax Dodder, which I have seen destroying very considerable portions of the Flax crop in England, Scotland, and Ireland. It is a plant which germinates in the ground, and sends up a slender threadlike stem, which, twisting itself about, soon touches one of the stems of the Flax amongst which it is growing. As soon as this takes place, the Dodder twists itself round the Flax, and throws out from the side next to its victim several small processes which penetrate the outer coat or cuticle of the Flax, and act as suckers, by which the parasitical Dodder appropriates to its own use the sap which has been prepared in the Flax, upon which the growth of the Flax depends. The Dodder then separates itself from the ground, and relies solely upon the Flax for its nourishment, producing long slender leafless stems, which attach themselves to each stem of Flax that comes in their way. Thus large masses of the crop are matted together, and so much weakened as to become almost useless. This plant

particular great quantities of seed which is usually threshed with the Flax-seed, and sown again with it in the succeeding year.

Several years since I took considerable trouble to ascertain if all foreign Flax-seed was mixed with that of the Dodder, and was led to the conclusion that the American Flax-seed is nearly free from this pest, and that that from Russia, and especially Odessa, is peculiarly infested with it. As this is a subject of much importance, I trust that the cultivators of Flax will turn their attention to it.—*Charles C. Babington, St. John's College, Cambridge.*

ON MINERAL & INORGANIC MANURES.—No. VI.

By Professor Charles Sprengel.

(*Translated from the German.*)

The duration of the action of lime manure depends, first, on the quantity used, and on several other circumstances, to be alluded to. If the amount of lime is calculated of which the soil is deprived by one harvest, it will be found that 500 lbs. per acre should be sufficient for many years; still the plants cannot absorb all the lime which has been brought on a field, because they do not penetrate with their roots every particle of earth; and a great part of the lime is also nearly lost to the plants by its combining with the hydrated silica contained in the soil, forming a compound insoluble in water. Another portion is dissolved by the rain and snow-water, so much, viz., as has combined with humic and carbonic acids into salts, which are soluble in water. The silicated lime, it is true, is again in its turn decomposed by the carbonic and humic acids of the soil, whereby humate and carbonate of lime will be formed; but this always takes place so slowly, that the plants cannot derive much benefit from it. These processes, therefore, fully explain why the manuring with lime needs to be repeated, and why its effect, although (by using large quantities) it may last 25 or 30 years, will not last with small ones more than 6 or 7 years. It is, moreover, to be considered that the salts, which are produced in the soil by manuring with lime, are generally difficultly soluble in water, and consequently that the soil must contain a considerable quantity of them, if they are to improve the growth of plants or aid their nourishment.

The ways in which lime is used as manure are different. Generally, small heaps are formed of it on a field previously ploughed; these heaps are covered very closely with a layer of earth, two or three inches thick, and the lime has to remain in that state until it has become slaked. These heaps are afterwards well worked up with the soil above and beneath; the lime is carefully spread, then harrowed and ploughed under about two inches deep; the land is then harrowed; then another ploughing, somewhat deeper than the first, is performed; and the whole operation is concluded by harrowing. Although this process is very simple, and requires little manual labour, it is not to be doubted that it is still imperfect. In the first place, as the heap soon becomes cracked by the swelling of the lime, it will not be protected by the earth from the influence of the atmospheric air, which will cause it to lose its caustic property; and consequently, when subsequently mixed with the soil, it will not act so powerfully on the organic matter and the coal of humus contained in it.

Another way of using lime is to throw it, at some short distance from the fields, into one or more large heaps, and to pour so much water upon it as entirely to slake it, and convert it at once into a powder. Three pounds of burnt lime will require for that purpose one pound of water; i. e., the two combine chemically in that proportion, and become converted into a dry, very fine powder. On the other hand, not too much water is to be taken, else a pap will be produced, which cannot be spread about, and which when dry will form a hard mortar. If some lumps of lime should not have been slaked, they are to be thrown aside, when the limedust is conveyed on the fields, and these again sprinkled over with water, and if they should not then fall to pieces, they are either not pure lime, or have not been sufficiently burnt, which can be easily ascertained by trying them with a little acid. The main object, after the lime has become slaked, is to spread it as soon as possible over the field, and to proceed with it as stated before; because everything depends on the lime coming in as caustic a state as possible on the ground, in order to accomplish what we expect.

The third method of manuring with lime is the following:—It is placed in conical heaps in alternate layers with vegetable mould, taking three or four parts of earth to one of lime, over which the necessary quantity of water is afterwards poured; the heap is then well covered either with turf or straw, over which some earth is to be thrown, and the whole left quiet for three or four weeks. Afterwards, the lime, which by this time has been converted into powder, and the vegetable mould are well worked up, and then carried on the field. There is no doubt that this method, provided earth be at hand, is to be preferred to any other, as all lime which has not combined with humic acid will remain caustic, and will act in the heap very powerfully on the coal of humus. The greatest amount of labour it occasions is fully repaid by the produce obtained, as a considerable quantity of humate of lime is produced, which, as we shall see hereafter, is a superior manure. Vegetable mould, however, is not to be had everywhere.

In some countries the slaked lime-powder is strewed over the clover-stubble, it is then shallow ploughed, and before Rye or Wheat is sown, the field is harrowed and ploughed several times. But it is not advisable, on any account, to strew the lime-powder over growing crops, because as it is soluble in water it easily corrodes the plants. It may, however, be used in that way on meadows on which much moss is growing, as it destroys those plants, and after it has united with the humic acid of the soil it will elicit Clover and sweet grasses.

It is also a general rule, never to manure with lime in wet weather, for it will then combine with the sand of the soil into mortar. If, however, the lime is once well mixed up with the soil, rainy weather is desirable, as it then soon becomes dissolved and thoroughly well mixed with the whole of the furrow-slice, and then acts strongly on humus, the organic matter, worms, &c. Lime is burnt in kilns variously constructed; wood, peat, brown or common coal being used as fuel. The chief point in the operation is not to expose it too soon to a great heat, and to supply the fuel uniformly. To let it cool before it is thoroughly burnt is always very injurious. If wood is used, the ashes obtained will yield a manure superior to the lime itself.

(*To be continued.*)

ON THE DESIRABLENESS OF EXPERIMENTAL FARMS.

It may reasonably be asked, what is the practical benefit likely to arise from the publication of experiments of which the results are not only various, but often contradictory, and which are, therefore, more likely to render the farmer sceptical as to any good that is to be derived from the use of the new manures, than to aid him in the choice of that best suited to his own case, or to teach him to calculate upon the result from any fixed principle by which he may judge of its applicability to his peculiar soil and situation. Professor Johnston, of the Durham University, remarks, in his clever and interesting lectures on Agricultural Chemistry, after giving a detail of many experiments with Nitrates, p. 491: "We are obviously in want of better and more numerous observations, especially in regard to Turnips. The above discordances will either vanish when we obtain a larger collection of results, or they will find an explanation in the more accurate observations we may expect to obtain in regard to the climate, soil, and geological portion of the locality in which the experiments are made." He then goes on to urge upon those practical men who are really desirous of promoting the vastly important work of Agricultural improvement, to be more minute, exact, and accurate, in the details of their experiments in these respects. These, doubtless, are objects of most desirable attainment, and I fully concur with Mr. Johnston in his wish and opinion on the subject; and I gladly avail myself of this opportunity to express my gratitude to him for the benefit he has conferred on Agriculture, by proving, like other philosophical men who are engaged in the same good work, its connection with, and dependence upon, those principles of science, without which its practice can never be subjected to fixed laws, or be secured against doubtful and unsatisfactory consequences. But if he entertains the hope that such information as he desires, involving the necessity in the party giving it, of scientific knowledge, acute observation, and philosophic research, is to be obtained from the practical farmer, I think I can safely forewarn him of his disappointment. The farmer, as such, is the least likely of all men to pursue such experiments to an impartial and accurate conclusion. His practice is founded upon the custom of his vicinity and his own observation and experience, but he is generally ignorant of the efficacy of chemical agents and too often prejudiced against any innovation of ancient habits—and were his knowledge and acquirements equal to the task, the time and attention necessary to conduct with due vigilance and accuracy such details and experiments are not at the command of the industrious, persevering, rent-paying farmer. He must secure his crop of Hay when the sun shines, instead of occupying himself with the minute investigation and comparative weight of one plot that had been manured with this, and another with that ingredient. He must attend a distant market at the time when, from the state of the weather or some other cause, some other experiment would have been most accurately tested, and the opportunity being lost, probably renders all the care previously bestowed upon it of no avail. Many other reasons might be adduced to prove that it would be visionary to expect such results from the mere farmer, and if by accident one should be found with taste, habits, and inclination for such pursuits, it might not be venturing a very rash conjecture to suggest that he would not be the first to attend the summons on the rent-day. But then there are other practical Agriculturists besides the rent-paying farmers. Where are the patriotic and science-loving owners of many broad acres—the amateur Cincinnati of our Agricultural day, who so zealously and so laudably bestow their time, attention, and means, in aiding the advancement of the most important national work of Agricultural improvement? That there are many such I gladly admit, and their exertions entitle them to the nation's esteem and gratitude—but it is not the business or the duty of any individual to subject himself to the labour and incur the responsibility of making experiments for the Agricultural world, through all the range of Agricultural science. He may so employ himself for his own information or amusement, and he may give the results the chance of publicity, but still there might be wanting that minute and rigorous investigation of all the qualities peculiar to the soil and situation, and that small yet influential variation in either, which may cause a certain kind of manure to be more or less applicable, or not at all so, to the object in view. This can only be discovered by a close chemical analysis of the soil as well as the manure, by which to ascertain, in what property necessary to its fertility the one is deficient, and which the other is calculated to supply. The farmer knows by experience that he cannot grow the same kind of crop in succession on the same land without a great falling off in produce, and that even with good management, his land, in time, become unproductive of certain crops when repeated at too short intervals—but it is for the chemical investigator to explain, of what peculiar property such crops have exhausted it, and what particular kind of manure is best calculated for its restoration, as well as to determine what preference certain classes of plants have for one kind of manure over others. An extensive course of experiments, well conducted under the direction of capable and scientific men, and their results published in a systematic manner, would afford to the farmer a dictionary of Agriculture by which he would know what effects to expect from the application of certain kinds of manure to certain descriptions of soil and crops, without working in the dark and trying for himself hap-hazard experiments too often ending in disappointment. But the question will be asked, how is this most desirable object to be attained? I confess that it seems to me to be quite within the reach of those zealous and influential gentlemen who have already effected so much in the establishment of an institution as yet so young, but still so wealthy and prosperous as the Royal English Agricultural Society. The undertaking would doubtless be attended with trouble and labour to those who should engage in it, and what public and useful work is exempt from them? but I cannot anticipate any insuperable difficulties, nor conceive of any object more worthy their attention and the appropriation of a part of their ample funds and resources than the establishment of one farm at least for the purpose of conducting experiments in Agriculture upon scientific principles, and on an extensive scale; such experiments to be conducted, as a matter of necessity, by some one or more persons thoroughly conversant with Chemistry, Geology, Botany, and the other branches of science bearing upon that object, and solely responsible, under the direction of a committee of management, for the truth and accuracy of their details and results. To enter into any particulars of the arrangements of such an institution would be premature at the present time. Certain examples of the kind do exist on the Continent of Europe, but they are in many respects defective, and capable of much improvement. This subject has been ably treated in an excellent article in the Journal of the English Agricultural Society, by Professor Daubeny, which it may be hoped will attract the attention it merits. If, in addition to an experimental farm founded by the English Agricultural Society, the National Societies of Scotland and Ireland would also follow its example, and if a regular interchange of communication were maintained between the scientific men at the head of each establishment, under some previously-arranged plan for conducting similar experiments; the variety of climate which the several institutions would necessarily embrace, and the variety of soil which natural circumstances, aided by a little care in the selection, must also afford, would give them ample means of detecting the latent influences which the variations of soil and climate are found to exercise on the vegetable and animal worlds. A summary and digest of their combined transactions, judiciously prepared for publication, would present to the public such a compendium of Agricultural knowledge, based upon scientific principles and reduced to practice, as it has never yet possessed, nor is ever likely to possess, but through some combination of elements equally extensive and equally powerful for good, as that which I have enumerated, and would add more to our information on this all-important subject in the ensuing ten years than is likely to be done by a century of unassisted and casual observation.—*Extracted, by permission, from a published "Account of Experiments, &c.," by John Grey, Esq., Dilston.*

ON GORSE, AS A WINTER FOOD FOR HORSES.

(*Continued from page 78.*)

Though almost every farmer in that part of Wales with which I am acquainted feeds his horses with Gorse if it grows naturally on any part of his land, a very small portion of them take the trouble of cultivating it for that purpose, except upon the tops of their fence-banks, for which use a considerable quantity of seed is imported from Ireland, the price fluctuating from 6*d.* to 1*s.* per lb. If any person cultivates it for sale, they prefer purchasing the crop of him at the rate of 20*l.* an acre, to the necessary outlay of capital, in raising a perennial supply of fodder, which occupies the soil for two or three years before it comes to its full value. At my suggestion, the managers of the Nantlle Railway sowed it upon the embankments of that work, with the double object of preventing slips and producing some return. The annual sale after the third year produced 100*l.*, and the rate, per acre, at which the better portions of the crop sold was what I have stated above. The purchasers were the small farmers, employed in carrying copper and slate from the mines and quarries in the vicinity. While staying in Norfolk, during a very dry summer, in which the Hay crops were greatly deficient, I proposed to a farmer, who was anticipating a want of fodder for his horses during the ensuing winter, to use for this purpose the Gorse which was growing in sufficient abundance on the fences of his farm and on the waste ground of the lanes surrounding it. I succeeded in convincing him of the value of it, but the prejudice of his men prevented his adopting the suggestion, and he preferred purchasing Hay at a high price. When land already under arable culture is intended to be laid down with Gorse, many of Otter's pipes taken with it, but they should be sown thin, or they will injure the young plants. The usual allowance of Gorse seed is from 12 to 15 lb. per acre. If intended to be sown upon rough land under pasture, the soil should be pared and burned, and a crop of Oats may be taken the first year, under the precautions I have mentioned. Should the land with this treatment be such that a heavy

crop of Oats may be expected, it will be better to delay the cutting of the Gorse for a year, and to take a second crop of Oats with it. The Gorse may either be sown broadcast or in drills; if the latter plan be adopted, the drills should be about a foot asunder. In the spring of the second year, a dressing of peat-ashes is found very beneficial; and it will be necessary to free the plant from coarse Grass and weeds, which would smother it during the summer. The same process will be occasionally advisable in after years, and, therefore, drills are to be preferred. It should also be defended from the bite of sheep and the trampling of cattle. It will hardly be worth cutting the following winter, but in the year after that, it will be nearly in full perfection, and will afford a supply from October to the end of April. The parts of the plant used are the succulent shoots of the preceding summer. It is not the general practice to cut it every year, but only every alternate year. In this case some of the woody portions of the plant are unavoidably mixed with the green shoots, and require to be separated from them. On the Nantlle Railway the Gorse was cut every year, for five or six years in succession, without any apparent diminution of produce, till towards the close of that period. When the crop begins to exhibit such indications, a year's rest will probably set it to rights again.

In Wales, the Gorse was formerly prepared for the horses either by pounding it by hand with a wooden mallet, or by means of a number of wooden stamps, set in motion by a water-wheel. Cast-iron gorse machines are now very generally substituted for these. They consist of a wooden trough, like that of a chaff-cutter, in which the shoots of the Gorse are laid, mixed with a little hay and straw, and the mixture is brought forward by means of two fluted cast-iron rollers, to meet an iron cylinder armed with knives, spirally disposed around it. Notwithstanding the spines of the Gorse, which are not destroyed by the process, horses delight in the food, and thrive upon it. They ought not to have much Corn with it, as it is rather heating in its nature. A riding mare belonging to Mr. S. Holland, of Plas Penrhyn, though in constant work, was always ready to throw up her heels and run away with him, her food consisting, during the winter, of only a bushel of Oats per week and as much Gorse as she would eat, having about a third of its weight of hay cut with it.

The cost of such a machine used to be about five pounds. It may be worked either by hand, or by a small water-wheel where there is a rill of water at command. For cows, it is necessary that the Gorse should be pounded to a pulp, to get rid of the spines, and a good machine for effecting this is a desideratum. Should any reader of this Journal, having a quantity of Gorse growing on the wastes around him, be disposed to try it as a winter food for his horses, and should he wish to purchase such a machine, I am sure that if he puts himself in communication either with Mr. William Turner, merchant, Caernarvon, Mr. Owen Jones, land-agent, of the same town, or Messrs. S. Holland, jun., and Co., slate quarry proprietors, Portmadoc, any of those gentlemen will have pleasure in procuring it and forwarding it by some of the numerous slate vessels which sail from the ports of that district to all parts of Great Britain and Ireland.

Were I wishing to introduce the use of Gorse as a food for horses belonging to me, knowing the prejudices of the men against any new kind of fodder, I should in the first instance confine the use of it to my own riding horse, satisfied that from seeing its effects, and the avidity with which it was eaten, they would soon, of their own accord, request a supply for the cattle under their care.—*J. Trimmer.*

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. V.

PART II.—*On the Chemical Constitution of Plants—as compared with that of the Soil—and the Necessity of adapting the Cultivation of the One to the known Composition of the Other.*

ALL living beings, animal or vegetable, have their life supported, their waste restored, and their maturity perfected by means of food, which possesses a chemical composition similar to their own.

In animals this food is obtained and digested by a peculiar series of organs, with which they are, according to their several habits, specially provided. They are termed organs of prehension (laying hold of food), mastication, deglutition, and digestion. Plants are the organizers or manufacturers of food for animals, and in them a simpler, but not less beautiful, system is provided. The Physiologist sees with exquisite pleasure, in the roots of plants, with their delicate spongioles or terminal suckers, which instinctively appropriate that part of the soil which is their natural food, and in the leaves with their respiratory system of cells, the rudimentary type of that higher organic system which in the animal creation obtains the most perfect development.

But the simplest, as well as the highest and most complex organization is equally destined to perform distinct and appropriate functions in the scale of living beings. If a plant and an animal that feeds upon it are taken into the laboratory of the chemist, their ultimate constituents will be found identical. And yet what a difference to the mental observer exists between the two! and how much greater still, appears the difference in their food! Yet, in reality, they are essentially the same.

The terms unorganized and organized matter explain the real difference in the food of each. The plant lives upon the elements of organic matter, and thus becomes an organic being. The animal lives upon the plant which its organic digestive and assimilative system converts into the muscle and bone, and the skin, hair, or feathers with which its body is covered.

But the ultimate analysis of bone and muscle, and plants, is identical. The plant deposits in the cells of its habitable structure certain mineral substances. The animal converts the lime or iron thus stored up into bone, or the colouring matter of blood! and thus plants become not only the organisers of animal food, but the depositories of principles essential to the perfect development of the animal.

Now, from these observations the reflecting observer will be convinced of the truth of the following propositions:—

1.—That a knowledge of the chemical composition of plants will enable us at once to select for them appropriate food; and

2.—That knowing the nature of the soil, and understanding the chemical composition of the plants he wishes to grow, the scientific farmer can, by increasing the quantity of appropriate food, increase to a certainty the weight or measure of his crop.

Theoretically, a grain of Wheat or Barley, a Mangold Wurtzel, a Turnip, or a Potato, can be increased in bulk as easily as an ox can be fattened in its stall. But the food appropriate for the tuber may not be, and indeed is not, that which is proper for the grain. The former contains more starch than albumen; the latter more albumen than starch. Is it not obvious then that the manure must be selected in accordance with the known composition of the crop, and still more in accordance with the known condition of the soil. I am the more anxious to dwell upon this point, because mistakes are daily committed, and Agricultural chemistry is brought into disrepute by the consequent failure of the experiment, which is made without regard to the very first principles that science professes to teach.

Plants, then, are the organizers of food for animals. To support animal life two kinds of food are indispensable—

1.—That which contains azote or nitrogen, and hence is called azotized food.

2.—That which does not contain azote, and is called non-azotized food.

The tissues of all plants, the stalks, leaves, roots, &c., are composed of non-azotized matter; they, therefore, must be fed with manure of a similar nature. But all plants upon which animals feed contain azotized matter, which is deposited in the cellular structure of the plant, more particularly of the seed, as in Wheat, Barley, Oats, Beans, Peas, &c. Now this azotized matter does not exist as a constituent of the soil; it must be added to it by the farmer. Thus, when a farmer spreads his field with the manure formed by his cattle in the straw-yard he supplies non-azotized food (the straw), for the production of the tissues of the plant—and azotized food (the urine); which after decomposing, the plant will organize and deposit in the cells of its structure—in the form of gluten, vegetable albumen, fibrine, legumen, &c., &c. The dung is principally useful in supplying the plant with phosphates, of which we shall speak hereafter.

In addition to the organic matter taken up by the roots in the form of non-azotized and azotized materials, there are certain inorganic substances also taken up, either to perfect the fabric of the plant, or with the ulterior design of being appropriated by the animal which feeds upon it. These inorganic matters are also deposited in the cellular structure of the plant.—*C. B. Bree, Stowmarket.*

(To be continued.)

Home Correspondence.

Effects of Drainage.—Observing in a late Number of your journal an account of the improvements in draining upon the estates of Lord Stair, I beg to state an instance of a farmer of my acquaintance, who has far exceeded the cases adduced on that nobleman's estates. Mr. Robert Ferguson, of Muirhouselaw, tenant to John Ord, Esq., a few years since entered upon a lease of 21 years for the above farm, a cold wet soil, which, though of considerable extent, seldom produced more than 20 to 25 diminutive stacks of corn, and other produce in proportion. During the first three years of the lease, Mr. Ferguson opened and laid in 120 miles of drains, all filled with stones taken from a quarry and broken small; a more expensive process than tile-draining, but at the same time greatly superior as regards efficiency. The expense of opening the drains was borne by the proprietor; and the expense of quarrying the stones, breaking, and filling the drains, was borne by the spirited tenant; and what has been the result,—the stackyard, instead of being only in part filled with a scanty produce, as formerly, is now quite insufficient to contain the crop, as Mr. F. is now able, on an average, to set up from 75 to 80 large handsome stacks of corn; hay, turnips, and other produce being in proportion. Let landlords give leases and encouragement to their tenants, that the soil may be put in a condition to bring forth abundant crops. We hear daily from those who are indisposed to lose sight of a shilling of their capital, that farming is an unprofitable occupation: I say to them, look at the example set them by the case now mentioned—and go and do likewise.—*W. D.*

Remarkable Case of a Cow that was swollen with Eating a Quantity of Swedish Turnip-tops.—The owner of the cow was alarmed by finding her swelled to an immense size, but waited till the beast was falling down before he applied any remedy; he then tapped her in the left loin, about two inches from the last rib, making an opening of about three inches, from which, by introducing his finger and thumb, he drew out about three quarters of a cwt. of undigested leaves, which, with the discharge of wind, rushing out as it did with great violence, was evidently a great and immediate relief to the animal. In few hours after, a plaster of pitch was placed over the wound, a dose of salts and, what is here called, Irish slate, was given daily with her own milk for a few days, and the cow is now, two months after the circumstance, as well as ever.—*E. C.*

Coprolites.—Professor Henslow, in his communication on Coprolites, in your last Number, expresses his surprise that I should, in my letter to you on the same subject, have supposed there might be some difficulty in distinguishing, by the external appearance, the true Coprolites from the pebbles, with which they certainly are sometimes associated. He adds, "a very slightly-practised eye could never make the mistake,"—and yet, Sir, the very specimens which I examined (and nearly half of which were but pebbles), were all exhibited on the table of the Geological Society as true Coprolites, and no one doubted but that they were so. From this fact, I think it may be inferred that, in some cases at least, the difficulty I allude to might exist. With respect to attrition accounting entirely for their rounded form, I did not intend giving that as my opinion, but that it has something to do with it is evident, from their being found on the beach associated with pebbles harder than themselves, in which situations, and in such company, it must infallibly happen that, moved by the ebbing and flowing of the tides, asperities must be the consequence.—*W. H. Potter.*

Zinc Vessels for the Dairy.—I have read a statement quoted from high authority that milk kept in zinc vessels is likely in summer, even within a very few hours, to become deleterious, by dissolving and holding in solution portions of the zinc. If this be so, the fact should be generally made known; for the substitution of zinc for leaden vessels has of late become frequent with dairymen on account of the less cost of the former, and their supposed quality of causing the separation of a greater proportion of cream. If any of your chemical friends can throw any light upon this subject, I, for one, shall be much obliged.—*A Dairyman, Aylesbury.*

Time of Manuring Grass-Land.—What is the best time of the year for applying farm-yard manure to Grass-land? there is a great variety of opinion, as well as practice, in this neighbourhood. Most people here seem to prefer putting it on in the spring, the objection to which is, that should the spring prove a dry one, the manure gets its goodness dried out of it, does very little good to the crop, and is a great annoyance in hay-time; others apply it late in the Autumn (after they have eaten off their after-grass), and then vegetation being dormant, the best of the manure is washed away and carried off by the drains without being of any service whatever. Here, with the help of irrigation and stimulants, I am able to get two crops of hay in the year, and my plan is, to put in the manure from the farm-yard as soon as the second crop is cleared, say in the middle of August; if, however, the weather should be dry at the time, it is not spread, but left in the heaps until the rains set in, when it is immediately spread, and at that time vegetation is so vigorous, that it is out of sight in a very short time. It appears to do so much more good that I think even when only one crop is obtained it is better to lose the after-grass (or the pasturage of it) rather than lose almost all the benefit of your manure; and so great is the difference produced between manuring in August and October, that here the former was grown over, and out of sight in a fortnight, while the latter is still as visible as on the day it was applied, and the stimulus it has given to vegetation is scarcely perceptible. It is much to be wished that some of our expert operators would turn their attention to hybridizing some of the Cerealia. I think that spring Wheat may be crossed with some of the more valuable kinds, and, if so, there is great reason to hope for early and good varieties.—*T. G.*

Large tracts of improvable land in various parts of England lie waste, only awaiting the application of skill, capital, and labour, to give an ample return for such expenditure. We have modern companies formed, and forming, for great efforts. Capital is abundant, and combined endeavour, the feature of our day. Could not a company be established for the cultivation of these waste portions of our island? "A National Agricultural Company," enlisting public confidence by the integrity of its directors and the cordial co-operation of our wealthy and enlightened nobles and commoners, would be most useful and profitable; and I scarcely need point to the gratitude and blessings which would be elicted from labourers, by such an undertaking wisely and judiciously conducted. Small landed proprietors, also, would cordially support such an endeavour to redeem the waste lands of England from the useless condition in which they at present lie.—*M.*

Bones.—In your *Agricultural Gazette* of the 13th inst. there is an article signed "E. R., Halifax," on the subject of boiled or unboiled bones, and in it he states "he had had a conversation with a respectable Scotch farmer in Roxburghshire, and having inquired of him if bones were still in great estimation in his neighbourhood, he replied, that for the last three or four years the farmers had neglected them altogether." I beg leave to state that your correspondent has been in this respect misinformed. I am a seller of bone-dust, and can prove during the last three or four years I have sold in the counties of Roxburghshire and Berwickshire a very large quantity. And I may add, with the exception of guano, that easily-adulterated manure being in some instances tried as an experiment, bones will be held in as great estimation as ever they were. —*Patrick Clay, Berwick.*

Destroying Thistles by Salt.—If a small quantity of common salt, say about a tea-spoonful, is taken between the fingers and thumb and placed on the centre of the Thistle, in a day or two it will turn black, and in the course of nine or ten days the root and every part of the plant will be destroyed. This is a cheap and certain method of destroying Thistles on land. One person will

as or many as five or six will set up in the usual way. The salt should be applied before the Thistles have attained a large size, and great care must be taken that it is not dropped amongst the Grass or other herbage, as it will destroy it also.—*J. M. T., Hillsborough, Ireland.*

Manure.—Besides giving a list of manures appropriate to each description of plants, it might be possible to establish the quantity requisite for each. Thus, supposing a plant grown in an inferior soil, a good plant of Wheat is found to contain certain ingredients in certain quantities, while on the soil in question it is found to contain only so much of some of them. Might not the soil be analysed, and such a proportion of suitable manure be added to it, so guided thus, we may assume to be required? If this could be done, each field in a farm, when analysed, might be registered, and thus there would be a ready and accurate means of knowing how to prepare a particular field for a particular crop. Something of this kind is already done by almost all farmers, but not upon sufficiently scientific principles. We know that this is also done, in a measure, by draining, by ploughing, by exposure of the soil either to heat or frost, and by various other means, which will all readily present themselves to the mind of a practical man. If I am correct in my theory, I should think that when a superabundance of any ingredient existed, which was not suitable to a particular crop, it might be temporarily neutralised by a manure of a suitable kind.—*M. B. G.* [We refer our correspondent to Dr. Daubeny's lecture on the application of science to Agriculture, in the 3d vol. of the "English Agricultural Society's Journal."]

Experiments on Manures.—I beg to forward you the results of an experiment made by myself, on a small scale, with some of the more simple fertilizing agents. The ground I had to work upon was in the corner of a field of very poor, sandy loam, with a mixture of cold clay. Eight perches, manured with 8 bushels of soot, produced of Carrots, 12 cwt.; 8 perches, manured with the scrapings of a wood-yard into which pigs and geese occasionally intrude, but which consisted mainly of well-decomposed sticks and leaves, and which was spread on the surface to the depth of 4 inches, produced of the same crop, 14 cwt. The same quantity of land, manured with 8 bushels of lime, 8 cwt.; 4 perches, dressed with the leaf-manure 6 inches thick, of Beet-root, 5 cwt.; while the same quantity of land, without manure, gave only 2 cwt. In reference to Beet-root, I may be permitted to remark, that it was proved here by experiment on the milch cows that those fed on this vegetable gave much better cream, and in larger quantity, than those fed on Hay, Turnips, Carrots, or Parsnips; and it has often been matter of surprise to me that the above-named root is not extensively cultivated by Agriculturists, since it contains abundance of saccharine and other nutritious matter, is eaten by all animals with avidity, and is of most easy cultivation.—*J. L. Knox, Swinton Gardens.*

Berberry Blight.—The mealy blight observed by your correspondent on the Berberry, is, Erysiphe penicillata, a very curious object under the microscope. In its early stage of growth, like other species of the genus, it has been described as an Oidium. The mildew on Peach-trees is, I believe, the same species with that which grows on Rose-trees, but it is very rarely perfected; though I have gathered full-grown specimens of Erysiphe pannosa late in the autumn on Peach twigs. This fungus is far more distantly related to the mildew of Wheat than the rust-coloured Berberry blight; therefore, if there is any connection between the two diseases, it must be one of a more remote nature. It is not, however, probable that it has anything to do with the question; for other plants, when covered with a species of Erysiphe, have never been observed to be injured.—*M. J. Berkeley.*

Flavour of Butter.—At this season of the year at least one-half of the butter made in the Agricultural counties is rendered disgusting to many, and more or less offensive to all palates, by the flavour of Turnips. The following is an old-fashioned but complete "antidote to the flavour imparted by Turnips to milk, cream, and butter." Make the strongest infusion of nitre, by pounding it in a mortar, and pouring boiling water upon it. Let a dessert-spoonful of this solution for every two gallons of milk be stirred up in the warm milk as soon as it is brought in, and all flavour of Turnips will be removed.—*A Wrauleydale Dairyman.*

Manure dropped in the Field.—Mr. Billington's remarks on this subject in your last Paper are very judicious; but the system he proposes, in my opinion, scarcely goes far enough, and appears chiefly adapted to small farms; besides that, his plan of spreading the droppings every day is liable to the objection that the action of the sun and wind will cause the evaporation of much of their richness, before the land can be benefited by it. I shall now proceed to detail a system I have pursued during four years with the greatest success, with manure dropped in the field. On one hundred acres of pasture-land, stocked with about sixty head of cattle, an old man and a boy collect all the manure dropped, and wheel it into heaps in convenient parts of the fields, where it is mixed with an equal quantity of soil (scourings of ditches, road-scrapings, or any other refuse, will do for this purpose), and every morning each heap is covered with soil to keep in all the moisture; the man and boy also take up all thistles and other weeds, and repair any fences that may be broken by the cattle. These heaps are laid on the poorest parts of the fields in winter time, at the rate of five tons per acre—this measure being so rich that if more is applied, it causes the grass to become so rank during the following summer, that the cattle will not touch it. The manure is carefully spread, and early in spring the land both harrowed and rolled. The results of this system are: 1st, all coarse tufts of Grass gradually disappear, and the Grass near the hedges becomes as sweet and palatable to the cattle as that in any other part of the fields; 2d, the land carries more stock; 3d, all weeds are eradicated, and their place supplied by good herbage. This year 18 acres have been manured with the droppings collected on the 100 acres mentioned above. The expense is as follows:—

	£	s.	d.
Wages of an old man and boy from May 16th, to Nov. 16th, (26 weeks); the man 9s., the boy 4s. 6d. per week—13s. 6d.	17	11	0
90 tons of good manure, sufficient to manure 18 acres at 6s.	27	0	0
Gain	£9	9	0

The practice of gathering and heaping the manure dropped in the fields has been long known to the Leicestershire and Northamptonshire graziers, from whom I borrowed the plan, merely adding the soil which, in my opinion, is a great improvement. So convinced am I of the great benefit derived from this practice, that it is my intention to adopt it on the whole of my grass-land, and I confidently recommend it to the notice of my brother farmers. —*R. F. S., Yorkshire.*

Gluten in Grain.—You quote from "Smith's Productive Farming" on this subject. It is true that the mode of cultivation may and does give rise, in some degree, to the different quantities of gluten in Wheat, Rye, and Barley; but from the article you quote it may be inferred that this is the primary, if not the only cause, which is not the fact. Climate is the principal cause of the difference of quantity of gluten in Wheat, as may be proved, if not by theory, by observation. We all know that for making biscuits Wheat is required with but a small proportion of gluten; thus we find Scotland produces flour famous for biscuits; and Naples produces flour famous for maccaroni, which requires a preponderance of gluten, and this flour contains so much gluten that bread from it is not good; hence the invention of maccaroni by the natives as a substitute for the bread of colder climates. I am aware that this observation does not accord with Sir Humphry Davy's statement of quantities of gluten in Wheat grown in different countries; thus he gives—

French Wheat	12 per cent. of gluten.
Bavarian Wheat	24 per cent. "
English Summer Wheat	24 per cent. "
Do. Winter do.	19 per cent. "
Sicilian	21 per cent. "
Barbary	19 per cent. "

In all the above examples the climate where the Wheat was grown should be ascertained; for example, to talk of French Wheat is an indefinite mode of speaking; it is French whether grown in the north or south, which possess vastly different climates, and a similar observation may be made on the other examples, for in every country climate depends on altitude, therefore the above examples say but little towards the establishment of any theory; but I believe it may be established by observation as a general rule that the cold climates produce the smaller quantity of gluten in Wheat, and the warmer the greater quantity.—*J. G.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A MONTHLY Council was held at the Society's House in Hanover-square on Wednesday last, the 7th of Feb.; present, the Right Hon. Earl Spencer, President, in the chair; his Royal Highness the Duke of Cambridge, his Grace the Duke of Richmond, Viscount Torrington, Hon. Robert Henry Clive, M.P.; Hon. Captain Spencer, Col. Austen, T. Raymond Barker, Esq., Samuel Bennett, Esq., W. R. Brown, Esq., French Burke, Esq., Colonel Challoner, F. Clifford Cherry, Esq., H. C. Compton, Esq., M.P.; Layton Cooke, Esq.; J. Evelyn Denison, Esq., M.P.; Humphrey Gibbs, Esq.; B. Brandreth Gibbs, Esq.; Stephen Grantham, Esq.; W. Goodenough Hayter, Esq., M.P.; W. Fisher Hobbs, Esq.; John Hudson, Esq.; W. H. Hyett, Esq.; John Kinder, Esq.; Fielder King, Esq.; William Miles, Esq., M.P.; Philip Pusey, Esq., M.P.; Francis Pym, Esq.; Professor Sewell; William Shaw, Esq.; J. Villiers Shelley, Esq.; and H. S. Thompson, Esq.

The minutes of the former monthly and special councils having been read, G. J. Bosanquet, Esq., of Broxbourn Bury, near Hoddesdon, Hertfordshire, was elected a Governor, and the following gentlemen Members of the Society:—

Kerrick, Edward, Arnolds, near Dorking, Surrey
Wray, John, 6, Suffolk-place, Pall Mall, East
Langdale, Marmaduke R., Mountfield, near Tonbridge Wells
Spurgin, Dr., Orplands, near Bradwell, Essex
Rogers, Langdon M., E.I.C. Service, Fitzroy Cottage, Highgate
Hankin, W., Heller's place, Bentworth, near Alton, Hants.
Meggison, George, 61, Cannon-street, City
White, James, Governland Farm, Isle of Wight

The names of candidates for election at the next meeting, amounting to 91 in number, were then read, together with the names of the members on whose proposition they were respectively nominated to the Council for admission into the Society.

FINANCES.—Mr. Raymond Barker, Chairman of the Finance Committee, presented to the Council the monthly report on the state of the funds of the Society, from which it appeared, that on the 31st of January the current cash-balance in the hands of Messrs. Drummond, the Society's bankers, amounted to 1,870*l.*, and the stock invested in the names of the trustees of the Society to 7,700*l.* The Report also announced the extensive distribution of the Cottage Tracts on Gardening and Cookery, among Agricultural labourers, through the medium of Members of the Society; the addition of Mr. Brandreth Gibbs and Mr. W. R. Browne to the House Committee; and the reception of a communication from the Certifying Barrister of Friendly Societies, informing the Council that the Society had been included in the list of Institutions entitled to exemption from county, borough, parochial, and other local rates on land and buildings.

CONDITIONS ON RESIGNATION.—The chairman of the Finance Committee then called the attention of the Council to the following paragraph in conclusion of the report:—"The Committee have had submitted to them the list of members expressing their desire to withdraw from the Society; many of whose letters contain simply an expression of such desire, while others assign reasons for their so doing, at variance with the fundamental rules of the Society. The Committee feel it their duty to recommend to the Council the acceptance of such resignations, upon the payment of the subscriptions due; but submit to the council that they cannot recognise such reasons as grounds for their withdrawal." The question was then put from the Chair, and the whole of the Report was unanimously confirmed by the Council.

SOUTHAMPTON MEETING.—Communications were received, and referred to the General Southampton Committee, from Mr. Mayes, the chairman of the Local Committee of the Corporation, expressing the readiness of the authorities at Southampton to co-operate with the Society in the preparations for the meeting; from Colonel Le Couteur, president of the Jersey, and Mr. Dobrée, president of the Guernsey, Agricultural Society, explanatory of conditions connected with the exhibition of cattle of the Channel Islands' breed; and from Mr. Matcham, agent of the South-Western Railway, offering to contract for the conveyance of all goods and implements, from the terminus of the Railway to the Show-Yard. Mr. Cuthbert Johnson presented to the Council the draft of a bill "to authorise the Society to inclose common or other open lands for the purposes of Show-Yards; to protect their property, and to suspend during a certain period the privileges of those who possess rights of common, and other claims to the land which may be from time to time occupied by the Society." The Council resolved, that their best thanks should be returned to Mr. Cuthbert Johnson, for this instance of his attention to the interests of the Society; but that having the assurance of unanimous votes of the commoners at two public meetings, convened by the Mayor, at Southampton, for the consideration of the question, and a full confidence in the cordial feeling manifested towards the Society in the promotion of its object at the ensuing meeting in July, by the inhabitants of that town and neighbourhood, they think the measure proposed would in every point of view be inexpedient.

ENTRY FOR EXHIBITION.—Mr. Raymond Barker, as Chairman of the Special Committee, appointed by the Council to inquire into the case of the parties charged with an attempt at the Derby Meeting to effect the entry of a churn by improper means after the date of entry had expired, and who had consequently been declared disqualified for future exhibition submitted to the Council the result of their inquiry. The report stated the explanation offered personally by the representative of the parties in question before the Committee, and concluded with the following paragraphs:—"Under all the circumstances, the Committee regret that they cannot find sufficient cause to recommend to the Council any alteration in their decision made on the 4th of August, 1843. The Committee are further of opinion that no by-law on the subject referred to them need be introduced, inasmuch as they conceive that whenever a case of fraud or gross impropriety is satisfactorily made out, the Society would, as a matter of course, without the authority of any by-law, visit such offence with its highest displeasure, and so far as it has authority, with punishment."

WEST INDIAN AGRICULTURE.—A letter was read from the Rev. Dr. Stewart, Hon. Secretary of the Jamaica Agricultural Society, requesting the favour of communication with the Society in reference to the common objects of Agricultural interest in England and the West Indian Colonies respectively; and this request being referred to the Journal Committee, the General Agricultural Association of Jamaica was declared a corresponding institution, and the Journals of the Society ordered for the Jamaica Association accordingly.

LIBRARY AND MUSEUM.—Mr. John Robert Hall, of Grove-end Road, St. John's Wood, offered to place at the disposal of the Society, at a valuation, the agricultural library of his brother, the late Mr. Webb Hall, of Bristol, originally formed by Mr. Arthur Young for the Board of Agriculture, and bestowed, on the discontinuance of that Board, on Mr. Webb Hall, their Secretary, in compensation for the loss of office he thereby sustained. This offer was referred by the Council to the consideration of the Journal Committee. Mr. Jardine, as executor of the late Rev. W. L. Rham, presented to the Society a Flemish plough, imported as a gift to the Society by Mr. Rham, and at present lying at the Custom-house. This present was accepted, with the best thanks of the Council. A letter was read from Mr. Agnew, of Manchester, expressing his hope to be able to present to the Society the large painting of the Society's trial of Implements at their country meeting, and which had been painted for him at an expense of 1000 guineas. The Duke of Richmond presented, on the part of Mr. Lewis, a map of Southampton, on a large scale; Mr. Layton Cooke, a copy of his work on the Value of Landed Property (illustrated by diagrams); and the Yorkshire Society a copy of the last part of their Transactions; for which, and numerous other presents, the best thanks of the Council were ordered. The Council decided that Dr. Playfair, as Consulting Chemist to the Society, should be requested to analyse, under the direction of the Journal Committee, the specimen of marl transmitted to the

Farmer as retarding, when present, the operation of marle-dust as a manure for land. The Council then adjourned to Wednesday next, the 14th of February.

FARMERS' CLUB.

Chepstow, Feb. 3.—The first monthly meeting of this club took place on Monday the 29th ult. The subject for discussion, "the best method of summer-feeding farm-horses," was introduced by Mr. J. Sandford, of Mountain, who read a paper from which we extract the following:—"The best and cheapest method of keeping farm-horses through the summer is to feed them on Lucerne. You will be enabled to cut the Lucerne three or four times through the summer; so that I think two acres of land of middling quality will be sufficient to keep four horses five months in the summer; and I should give the Lucerne to the horses out of doors; I mean in cribs in a fold-yard where there is a shed, instead of in the stable; this being, I think, more healthy for the horses, and it is less trouble also. I prefer Lucerne to any other summer food, knowing it is quite as good, or better keep than Vetches; and it is also much cheaper, and when you have once got a fair plant of Lucerne, it is much more sure than Vetches, the winter or slug sometimes destroying the Vetch-crop, but not the Lucerne. Lucerne will last in the same land 20 years in as great vigour as ever, mowing three and sometimes four times in a season. Its cheapness will be evident from the following calculation:—Take four acres of middling land for Vetches, which I consider equal to keep four horses five months. Now I shall charge two of these acres at half the full rent, &c., because the Vetches will be off in time to sow Turnips, and the other two acres I shall charge at the full rate, being too late to sow Turnips; and I shall take two acres of Lucerne, which I consider equal to keep four horses five months, the same quality of land, and at the same price per acre:

Two acres for Vetches, including rent, tithes, and taxes, at 30s. per acre	£3	0	0
Two ditto ditto cleared for Turnips	1	10	0
Seed for four acres, 10 bushels at 7s.	3	10	0
Sowing and harrowing four acres at 5s.	1	0	0
Cutting four acres	0	8	0
	9	8	0
Per horse for five months	£2	7	0

Two acres Lucerne, including rent, tithes, and taxes	£3	0	0
Cutting three times, 2s. per acre	0	12	0
Allowance for seed per year	0	4	0
	3	16	0
Per horse for five months	£0	19	0"

The discussion then turned on the best manner of cultivating Lucerne. Mr. John Sandford and myself advocated the broadcast system, one of our reasons being that we consider hoeing likely to injure the crown of the root, which in this plant spreads considerably after the first year, and sends up shoots all round; and provided the land is quite clean when the Lucerne is sown, we think that it is likely to thrive better for any little surface grass that may come among the plants, as this tends to keep the ground cooler, which we consider preferable to exposing the surface of the soil to the hot summer sun. Several of the members stated they had tried manure on Lucerne without any apparent effect. I manured two ridges with guano last summer, at the rate of two cwt. to the acre, but there was no visible effect produced on the Lucerne plant.—*A. Hall.*

Reviews.

Advice as to the proper Management of your Farms. Dublin: N. Clarke, Printer, 50, Great Britain-street.

This is a handbill which has been printed for circulation among the small farmers of Ireland.

The writer of this paper opens his subject thus:—"The manner in which you manage your farms at present is so bad that the land is not improved, and the rent is paid with difficulty. It is generally this,—you manure for a crop of Potatoes, then take as many Corn-crops as the land will bear, and then let it out to rest."

He then states that in Scotland and England this system has been generally abandoned, and it has been found possible to keep the ground constantly giving crops, and yet improving by growing Corn and green-crops alternately, the latter being manured. Food, he further states, is economized and manure saved by the practice of house-feeding. "With proper management two acres ought to feed three cows all the year round," and "the produce of butter alone ought to pay your rent, and leave the Pigs, Corn, and Potatoes for your own consumption."

Four different courses of cropping are then suggested, varying according to the size of the farm.

On a very small farm the course recommended is,—1st year, Potatoes in drills, with Cabbages planted between in June; 2d year, Oats laid down with Clover; 3d year, Clover, for soiling; 4th year, Oats, followed by Rape, and Vetches followed by Turnips. On a farm of six acres the course is to be a little varied; and on a larger farm a seven-course system is recommended for adoption. Valuable advice follows on the preservation of every description of solid and liquid manure produced, and on the use of bone-dust and lime, the application of the former of which, it appears, would cost the Irish farmer 5*l.* per acre.

Lastly, we have instructions for the cultivation of Potatoes, Mangold-Wurtzel, Turnips, Rape, Cabbages, Wheat, Oats, Barley, Red Clover, and Vetches.

Without a practical knowledge of the soil and climate of Ireland, of the system of culture generally adopted by the small farmers, and of their circumstances, it would be rash to offer an unqualified opinion on the advice given to them in this paper. Still we can scarcely err in acknowledging that the system it recommends, in its general principles, may be applied to a considerable variety of soils, and is one of the best that a small farmer could pursue.

The grand feature of the system is the growth of green and Corn crops alternately, so that an abundant stock may be carried, and a good supply of manure produced on the land. The principle of the alternate system is recognised as sound by the best farmers of England, but it is far from being generally adopted. There are districts which produce comparatively little but Corn, and in which the soil is said, probably with reason, to be too stiff for the growth of Turnips. Many such soils would be greatly altered in their texture and converted into friable loams, by thorough drainage and deep perfect cultivation. We cannot hope, however, to see them thus improved without great additional capital being applied to them, and this additional capital will not be applied without good security for a return. It is astonishing how much capital might be applied with advantage to a small quantity of land, if there were a certainty that the cultivator would reap the full fruits of his capital and industry; and we do not believe that the practice of Agriculture will be much further improved in this country till measures of some kind are adopted to give full scope for the employment of capital, knowledge, and industry in the thorough cultivation of land. Theoretical knowledge of Agriculture may be increased, but how is the farmer to apply his knowledge without the requisite means and the requisite security?

Those in the situation of the small Irish farmer, holding but a few acres of land, are, perhaps, the most likely to improve it in a high degree, if placed in a right position. Their land should be thoroughly drained; they should adopt some such system of cropping as that recommended in the paper before us, and they should cultivate their soil thoroughly by the spade or fork. What business has a plough on a farm of six or seven acres? However desirable or necessary this implement may be on a large scale, it must be generally acknowledged that it is an imperfect machine, and that although, like other machinery, it will enable a man to accomplish more work in a given time than the simpler tool, it will not enable him to perform that work better or even equally well. A soil which has been thoroughly worked to a depth of 12 or 14 inches with the spade is in a state to which repeated ploughings would not bring it, even if the subsoil-plough were used, while the expense of cultivating land with the plough and subsoil-plough to a good depth is little, if at all less than would be incurred by manual labour.

The writer of the paper before us recommends that Rape be sown in June, and transplanted after the Corn-crop, to afford food for winter and spring. I have never tried this plan, but I have transplanted Swede Turnips to follow Vetches, and I think the practice in some cases a good one. A small seed-bed will supply plants for an acre. The seed should be sown in the spring thickly, and the Turnips transplanted when about the size of young Cabbage-plants, care being taken that the root is put into the ground straight, and not bent at the tip. If this precaution is not observed, the growth of the root will generally be much impeded, or altogether stopped. The chief advantages of this practice are, that the ground is not required till much later for the crop, and all risk of serious injury from the fly is obviated. With respect to Rape, the following circumstance may be mentioned:—A small patch of Rape was sown, for an experiment, about the latter end of September, 1842. It went to seed in the spring, but about the end of March the first crop was consumed. Liquid manure was then applied, and the ground was loosened between the rows; and about the latter end of May another good crop was taken. The ground was shortly afterwards broken up. This experiment indicates that Rape would be valuable as an early crop for cows or sheep. Although light, it occupies the ground at a season when it can be best spared. It would probably not be desirable, however, to take more than a first cutting in March.

Although bone-dust is undoubtedly a powerful manure, and may be a desirable application to some land, yet for farmers who have plenty of manure from their stock, as those following the proposed system would, the expediency of applying it at an expense of 5*l.* per acre must be very doubtful.

The cutting of Potato-sets is alluded to. Ought Potatoes to be cut, or planted whole? Has this question ever been definitively set at rest? The results of an experiment which was performed in our neighbourhood favoured the practice of planting whole, but no safe conclusion can be grounded in Agriculture upon a single experiment, and that, too, on a very small scale. We should like to see the relation between the size and state of the Potato-set, and the vigour of the future plant accurately determined.

A brief summary has now been given of the contents of this valuable paper; the leading principles of the system of culture it recommends have been pointed out, and a few remarks suggested by some of its details have been offered. It is well worthy of being circulated among the small farmers of Ireland, and of England also. If there is one point in which the advice is defective, it is in the omission of a recommendation to cultivate the ground with men and spades, or forks, rather than with horses and ploughs.—*H. F. F.*

Miscellaneous.

Mode in which Manures act.—It has been most satisfactorily proved that there are at least two distinct ways in which manures may produce crops. 1st. It may itself yield the elements of the crops, and hence, in this instance, the crop is merely the manure in a different form. Or, 2d. It may enable the crops to obtain their elementary ingredients with greater facility from the soil, in which case, of course, the increased crop, though produced through the agency of the manure, is really obtained at the expense of the soil.—*Dr. Madden on the Advantages of Extended Chemical Analysis to Agriculture.*

Recipe for Wounds, &c.—I can with the greatest confidence recommend the following recipe for cuts, galls, and broken knees, Compound Tincture of Benzoin, Tincture of Myrrh, each one ounce, Nitrous Acid two drachms—mix in a bottle for use. Apply with feather or syringe if the wound be deep.—*H. F. Odlum.*—*Dublin Farmer's Gazette.*

Application of Manure to Turnips.—The following Table shows the result of an experiment, alluded to in a former report, in growing Swedish Turnips with four different kinds of manure, which was this season made by Mr. Grieve, the intelligent land-steward of Mrs. Ferguson of Dirleton, and on whose perfect accuracy every confidence may be placed. The Turnips were sown on the 20th of May, and lifted and weighed on the 27th November last. The field on which they were grown had, until lately, been time immemorial in Grass, the soil being a dry friable loam. The value of the different manures speaks for itself; but it should be noticed that where the guano was used the Turnips seemed to braird more rapidly, were earlier ready for the hoe, and kept ahead of the others to the end, as if they had been sown at least a fortnight sooner.

Kinds and Quantities of Manures used per acre.	Price of Manure per acre.	Weight of Turnips, without roots or tops.			Weight of roots and tops.			Weight of rotten Turnips.			Weight of Total Produce per acre.

—*Scotsman.*

Notices to Correspondents.

Our Correspondents will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

Communications from the following Correspondents are in type, and are only waiting till room can be found for them:—*A Subscriber, A Perthshire Farmer, T. E., G., J. Caird, E. M., A Surrey Farmer, Yeoman,* and *A. Hall.*

Agricultural Chemistry.—*T. Butler.*—Analyses of soils are rarely useful, unless they enter so perfectly into detail, and therefore require such skill, as entails great expense upon the operation. It is very questionable, we think, whether gentlemen, though of known ability, would obtain sufficient practice in this way to justify them in devoting their whole time to Agricultural chemists.

Agricultural Gazette.—*Bungay.*—Send us a post-office order for 6*s.* 6*d.*, and we will take care that you are supplied at that price.

Application of Lime.—*An Amateur Farmer.*—You are right in not applying lime at present to the land under the circumstances which you describe. But you have, we think, trenched your land rather too boldly. You should have kept the top soil uppermost. However, the 60 yards of manure per acre will probably give you a good crop of Oats and Grass.

Burthens on Land.—*An Inquirer.*—We cannot obtain for you the actual sum per acre to which these on an average amount in England and Scotland; but the advantage which Scotch farmers possess over English in this respect, probably does not lie in their average payment as rent, being less for similar land. The amount of poor's-rate, road and church-rates, &c., as well as the annual sum paid to the landlord, are all taken into account by the English farmer before he enters on his farm, and they must, therefore, all be considered as rent, and this rent will be found generally to be proportioned *alike* in England and Scotland, under similar circumstances, to the quality of land. But the advantage possessed by the Scotch over the English farmer lies in his rent being generally variable according to the price of produce; while of that paid by the English farmer, the landlord's portion is almost universally a fixed money-payment; while of the rest, which is sometimes the larger half, the greater part—that paid to the poor—varies *inversely* as the price of produce, being greatest in amount when Corn is lowest. You were right, when speaking of the burthens on the English farmer, as compared with those on the Scotch, in calling them "vexatious" rather than heavy.

Drainage.—*James Denham.*—Please to give the address of the party who would give the required information.——*A New Subscriber.*—We are aware of no work exclusively upon the drainage of high lands. On drainage in general, see a pamphlet by Mr. Smith, of Deanston, and an Essay in the present Number of the English Agricultural Society's Journal. We should be glad to publish a statement specifying the character of the land, that of the limestone, &c., and the amount of benefit derived from the practice of manuring your vale lands with crushed limestone. We never heard of the practice before, with a compact limestone. We doubt whether, where coal is so near, burning lime is not the cheapest method of reducing it to powder. Low's "Elements of Practical Agriculture" is one of the best general treatises on the subject. Those you allude to are, however, both valuable works.

Dressing for Mossy Land.—*H. W. B.*—If you have not good farm-yard manure apply lime. The rushes will gradually disappear if the land is efficiently drained. If, instead of burning the refuse bark of the tan-yard, you were to soak it with liquid manure, you would obtain a valuable compost.

Gas-water.—*Wem.*—Soak the tan with gas-water, and turn it frequently. The addition of sulphuric acid to the water will form in it the sulphate of ammonia. We do not know how this is manufactured on the large scale, but will endeavour to ascertain for you.

Gold of Pleasure.—*Anonymous.*—"Almost all Cruciferous plants yield more or less of oil. One of these, Camelina sativa, cultivated Camelina (Gold of Pleasure), is a plant produced in various parts of Germany and Italy for this purpose. This plant is an annual, and is raised with facility. It grows spontaneously over a great part of Europe, and is a frequent weed amongst Flax. It grows best on light, sandy soils, and in the south of Europe two crops of it can be procured within the year. The oil it produces is said to be fine in quality, retaining a good flavour, and in burning it does not

produce any disagreeable odour. In the south of Europe it is sown in April or May, and is sometimes ready in less than three months, so that it is one of the quickest-growing of the oleaginous plants. The seeds are sown thin, and the plants hoed, if too thick. It is pulled or cut, and laid in a covered place, to complete the ripening and drying of the seeds. These being then freed from the stalks, by beating, are winnowed, dried, and buttered."—*Professor Low's Elements of Practical Agriculture.*

Onion.—*J. D. N.*—Old bushes must be cut or burnt down, and the young sprouts used as food.

Guano for Potatoes.—*H. T. H.*—See our answer to *A Young Rural*. If your land is in anything like good condition, you may expect a good crop of Oats after the Potatoes; but you should aim to get your crops, and especially your grain-crops, to depend a good deal upon the general condition of the land, rather than upon the particular manuring of the year.

Manganic Constituents of the Onion Tribe.—*T. Price.*—We have been informed, since last week, of an analysis of the Onion performed by Fourcroy and Vauquelin. A large quantity of uncrystallisable sugar was found in recent Onion juice, together with mucilage and the phosphate and nitrate of lime.

Liquid Manure.—*S. L. B.*—Apply liquid manure to Grass in April, and to growing crops of roots or Corn in the early stages of their growth.

Steeping Barley.—*J. B. N.* recommends the trial of chloride of lime in solution, as a steep for barley, to force on the sprouting. It would have this effect, but we doubt whether it would not at the same time injure the Malt.

Manures.—*Villager.*—Nothing is better than good and well-made farm-yard manure; apply it at the rate of 20 cubic yards an acre, plough or dig it in.——*Carlingill.*—Differences in the effects which follow apparently similar applications cannot be accounted for except by one who knows accurately the composition of the soils on which they were made, &c. The immediate contact of lime will injure the action of the guano by so much as that action depends upon the presence of salts of ammonia, for lime will displace ammonia from any of its salts and volatilise it. And to this probably the difference between you and your neighbours in your experience of guano is owing. We believe urate is made by soaking gypsum in the water of the stables and feeding-stalls.——*A Young Rural.*—Shavings, &c., are hardly worth going for; they may, however, be usefully applied in strong land. They are not worth more than 1*s.* per cart-load. Tanners' bark, when burnt, makes good wood-ashes, and it is then fit to mix with guano for a Potato-crop; but we should prefer soaking the rotten tan with liquid manure, and then mixing 3 cwt. of guano with 10 cart-loads of it as a manuring, in the ordinary way per acre, for Potatoes. 6*d.* per bushel is a fair price for soot, and the same for wood-ashes. Two of soil and one of guano would make a good mixture, but try rotten bark soaked with urine, instead of earth. You should have applied your guano to the Turnips before the Barley, and these should have been eaten off with sheep; you would then have been sure both of Barley and seeds. As it is, if your land is in good order, you may depend upon the guano for the seeds. We shall give an account of the cultivation of the Parsnep before the season for sowing it.

Manure.—*C. C. R.*—We are much obliged by your anxiety to get us right on this subject—correctness in market reports is of first importance to an Agricultural paper; but to show you that genuine accuracy in the actual prices quoted is not of so much importance as accuracy in describing the general state of the markets, as to whether prices are falling or rising, we may mention that within the past fortnight we have sold nearly 100 quarters of good white Wheat, averaging 61 lbs. a bushel, at 45*s.* This is 100 miles from London, and probably the majority of our readers are at a still greater distance, where prices, though they may rise and fall with those of Mark-lane, as they do here, are even less likely to resemble them in actual amount. Do not infer from these remarks that we are not fully anxious to report the Markets correctly. We cannot suppose that Messrs. Kingford and Lay would append their names to an inaccurate statement; mistakes may, however, have been accidentally made in it, and we shall communicate with those gentlemen on the subject. With regard to the publication of a Farming Calendar, we shall endeavour to supply its place, this year, at any rate, by making our Leader have a general bearing upon the operations of the season.

Mineral Manures.—*John W. Lloyd.*—We have seen your analysis before, published in the *Derbyshire Courier*. If you were to take a specimen of any ordinary soil, you would find on analysis that it contained all the ingredients mentioned as existing in your rock, and the most valuable of those ingredients in larger quantity. Is the soil above this rock extraordinarily fertile? It must be so, if your theory is correct. Our opinion is, that your land would not benefit much by an application of it, though ground to a powder. We shall return to this subject at greater length hereafter.

Plaster for Ploughing in as Manure.—*L. Stephenson.*—We can recommend nothing better for this purpose than the common Tare or Vetch. It is commonly used in this way here, by poor people, as a substitute for manure in their gardens. They obtain seed from those who have been accustomed to sow it early in autumn. You had better obtain some which has thus acquired hardiness and a habit of early growth; and, if you sow early, you may dig or plough it in by the 1st of May.

Potatoes.—*J. H. H.*—Farm-yard manure is most likely to be the best application, because it is the most compound of any. An analysis of the soil is not likely to be sufficiently delicate to point out the deficiency. If the land is tired of Potatoes, you should grow other crops on it for a while. The tubers contain in 100,000 parts, 290 of potash, 234 of soda, 33 of lime, 32 of magnesia, 5 of alumina, 2½ of iron, 9½ of silica, 54 of sulphuric and 40 of phosphoric acids, 15½ of chlorine, 37 of azote, and 20,035 of water and carbon (Sprengel). We do not know any analysis of the leaves.

Salt and Bugs.—*A Subscriber.*—The usefulness of salt as a manure depends on your soil being destitute of it. If you are in an inland situation, 1 cwt. per acre may be beneficially applied. Try it mixed with the manure in your compost heap. 20 or 40 bushels of soot per acre is the usual application. Crosskill's clodcrusher is stated by some of the writers in the current No. of the "English Agricultural Society's Journal," to prevent the ravages of the wireworm; we have no experience on this subject ourselves. No previous steeping of seeds will ensure the safety of the plant.

Turpentine Bugs.—*Rusticus.*—See answer to your question above. It will answer very well to soak earth, sawdust, refuse bark of the tan-yard, &c., with the solution of superphosphate of lime.——*Gentleman Farmer.*—We hope to hear from Mr. Campbell on this subject shortly, and will then answer you fully. Meanwhile, we think Oats should be soaked as long as Wheat, Turnip-seed as long as Clover, Mangold-Wurtzel 24 hours; Beans, Peas, and Tares, at least 48 hours; but you can try this in a wine-glass yourself some days before you sow in the field, stopping the soaking when the seed begins to swell. 200 lbs. of Wheat will take up 3 or 4 lbs. of any salt in a sufficiently strong solution. A bushel of Wheat, weighing 60 lbs., will only take up 2 or 3 lbs. In order, however, to be sure that you have enough, take 5 lbs. of the salt, and dissolve it in such a quantity of water as will perfectly cover the seed, and then place the bushel of seed in it. The "exact neutralization" of the acid, by adding to it a carbonate of any alkali, takes place, when, without an excess of the carbonate, the acid no longer reddens a piece of litmus paper. The substance in solution thus formed is then a neutral salt. You had better sow as soon as possible after steeping the seed; if dried again, as it will need to be if you drill the seed, it must be by the simple action of sun and air, lest it can be hoed in though wet. Clay land will not be ready for some time, and as the Wheat will be sown in spring, we shall use one bushel in the half an acre of ground. Had it been done in autumn, 1½ bushels per acre would have been plenty. We shall adopt your suggestion about the mineral constituents of plants.

Subsoiling.—*A. W.*—You were right in subsoiling light gravelly Turnip land; you will probably be benefited by it, in the greater depth of active soil you will thus ultimately obtain, and in the greater independence of dry weather which you have thus obtained for plants growing on it. Guano will likely suit your land, and perhaps your best way will be to sow 2 cwt. of it per acre over the growing Wheat, just before you hoe it in spring; but on a light soil you ought to make enough manure on your own farm, without going elsewhere for it. Bog-earth will act both chemically and mechanically in retaining the volatile ingredients of your manure. The addition of salt will not impair this action, and it may perhaps be useful on its own account, being alone its efficiency as a fixer of ammonia. For answer about the steeping of seeds, see above on that subject.

Sulphuric Acid.—Bones.—*White.*—We informed an anonymous correspondent last week that sulphuric acid costs from 1½*d.* to 2*d.* per lb. We have since been informed that it may be obtained in any quantity from Gibbs' Chemical Works, Bristol, at 1*d.* per lb. To any weight of bone-dust add three-fourths that weight of sulphuric acid diluted with its weight of water; let the two act on one another for a day, and then mix it all up together with a lot of dry earth, and apply at the rate of about four bushels of the bone-dust per acre. A simple way of estimating the proportion in which the chief elements of the soil stand to one another is to be found in Mr. Rham's paper on the subject, in the English Agricultural Society's Journal, from which we extract the following:—"Take a glass tube 2 of an inch in internal diameter, and 3 feet long; fit a cork into one end, and set it upright; fill it half full of pure water; take nearly as much water as has been poured into the tube, and mix with it the portion of soil which is to be examined, in quantity not more than will occupy 6 inches of the tube, and let it stand in a corner of a room, or support it upright in any way. In half an hour it may be examined. The earths will have been deposited according to the size and specific gravity of their particles. The portion still suspended in the water may be allowed to settle; and there will appear in the tube layers of sand, clay, and humus, which may be measured by a scale, and thus their proportions nearly ascertained." Manures cannot be analysed in this simple manner, but means will shortly be published for detecting adulterations in many of them.

Taste of Turnips in Butter.—*A Ross-shire Lady.*—See a paragraph on this subject in our Home Correspondence. If saltpetre will not effect the desired object—many say that it will—there is no remedy but altering the food given to the cows. Mangold Wurtzel will not affect the taste of the butter.

Weeds.—*S. K.*—We are not aware of any publication on this subject by Dr. Daubeny or Professor Henslow. A series of articles on the Weeds of Agriculture will shortly appear in our columns. Try sowing 1 cwt. of salt per acre over your Grass land. The constituents of guano very much in quantity in different specimens. The first analysis of it was by Klaproth. He found it to consist of—

Urate of ammonia	16 per cent.
Phosphate of lime	10
Oxalate of lime	12.75
Silica	4
Common salt	0. 5
Sand	28
Water and combustible matter	28.75
	100

"The word 'guano' is Peruvian, meaning dung. It is pronounced *Huano* by the Peruvians, which the Spaniards, according to the genius of their language, spell 'guano.'" You had better make a compost with the gas-water, as already described in this Paper. The refuse bark of the tan-yard will do very well to soak with it.

Weight of Crops.—*M.*—Twenty tons of Swedish Turnips and ten tons of Potatoes may be considered good average crops in any of the best counties in England. We have known of 30 tons of the former, and 18 tons of the latter produced per acre under field-culture.

Miscellaneous.—*Bridport.*—The volume for 1843 may be had, price 8*s.*, in boards.

*** As usual, many communications have been received too late for answering this week.

Markets.

SMITHFIELD, Monday, Feb. 5.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	10	to 4s	2	Best Downs & Half-breds	4s	0 to 4s 6
Best Short Horns	3	6	3	10	Best Long-wools	4	0 4 2
Second quality *Beasts*	3	0	3	4	Ewes and second quality	3	6 3 8
Calves	4	6	5	4	Pigs	3	8 4 4

On the whole, our trade to day has an improved aspect; there is, however, much disappointment in the Beast market, the moderate supply leading us to expect an advance in price, which could not be generally realised. Our best qualities found ready purchasers, at perhaps a shade beyond last week's statement, but nothing quotable; the Short-horns and second qualities were a heavy trade at former rates. Calves remain steady. Small Porkers of good quality are a little better sale.

Numbers.—Beasts, 2705; Sheep, 24,400; Calves, 65; Pigs, 280.

FRIDAY, Feb. 9.

There is but little variation to-day from our Monday's report. The supply is short, and everything finds a cheerful trade at about the same rates, with the exception of Veal. The late high prices of this article have had the effect of increasing the supply, and also of decreasing the consumption; these circumstances have caused a slack demand and reduction in price, the very best Calves not making any more than 5*s.* per 8 lbs., and many of good useful quality are sold at considerably less money. Monday and to-day we have noticed several short Sheep, but as the present prices of Mutton are mainly attributable to the advance in wool, they are a heavy trade. The weather is much too cold for short Sheep.

Numbers.—Beasts, 638; Sheep, 2800; Calves, 164; Pigs, 220.

41, West Smithfield

POTATOES.—Southwark Waterside, Feb. 5.

The supply during the past week has been moderate, but fully equal to the demand. The first two days having been extraordinarily fine caused a great depression in our market, and several consignats of cargoes that have been some time in the market went off heavily, and the annexed prices were barely maintained. The last four days have been frosty, attended with snow, but the change of weather has not at present increased the demand, the tendency having been rather downwards than otherwise; but a continuance of cold weather must check vegetation, and would, consequently, increase the demand for Potatoes.

WOOL.—Brittish, Friday, Feb. 9.

Our English Wool Market continues steady. There is evidently a disposition on the part of our large consumers to abstain from buying for the present, unless they can do so at the present rates. Our Colonial Wool Sales closed on Wednesday evening as advertised rather on the preceding sales.

Prices Current.

James Bennet, Wool Broker.

MARK LANE, Friday, February 9.—We have been scantily supplied with English Wheat during the week, and the few samples at market this morning obtained the extreme rates of Monday. Free Foreign is held at rather more money, but scarcely any business has been transacted in it. There continues to be buyers of Bonded Wheat, floating cargoes, and for shipment, at the full prices hitherto paid.—In Barley, Beans, and Peas we observe no alteration.—Oats are a very slow sale, and the turn cheaper.

Kinnerson and Lay.

COVENT GARDEN, Feb. 9.—Notwithstanding the extremely changeable state of the weather during the week, the market has been, generally speaking, well supplied; but trade still continues dull. There is a slight alteration in the price of Pine-Apples, which consist principally of Queens and Black Jamaicas. Grapes are offered at nearly the same prices as last week. Good dessert Pears still continue scarce; but Apples are sufficient for the demand; they have rather advanced in price since our last report. A good many foreign ones have appeared in the market during the week. Oranges are good and plentiful; they have diminished a little in price, being offered at from 6*d.* to 1*s.* 6*d.* per dozen. Lemons are plentiful, and are also a little reduced in price since our last report. Chesnuts are selling at from 3*s.* to 6*s.* per peck. The severe frosts have been rather unfavourable to the more tender kinds of vegetable. Broccoli, however, is sufficient for the demand. French Beans are slightly advanced in price; they are offered at from 3*s.* to 4*s.* 6*d.* per 100. Cabbages and Brussels Sprouts are abundant; Greens bring from 2*s.* to 4*s.* 6*d.* per dozen. Celery has a little advanced in price, as has also Endive; the latter is offered at from 1*s.* to 2*s.* 6*d.* per score. Seakale is good in quality, but is rather scarce. Asparagus is sufficient to meet the demand. Lettuces are selling at nearly the same prices as last week. A few good Cucumbers have been brought to the market during the week; they are offered at from 6*s.* to 9*s.* each. Cut flowers chiefly consist of Erica transparens and arborea, Euphorbia jacquiniflora, Lachenalia tricolor, Bignonia venusta, Acachlanthus grandiflorus, Cypripedium venustum, Acacias, Azaleas, Rhododendrons, Camellias, Tulips, Pelargoniums, Cinerarias, Primulas, and Roses.

FRUITS.

Pine Apple, per lb., 1*s.* to 12*s.*
Grapes, Portugal, per lb. 1*s.* to 2*s.* 6*d.*
Apples, dessert, p. bush. 8*s.* to 20*s.*

Shallots, per lb., 6*d.* to 9*d.*
Chills, per 100, 1*s.* to 2*s.*
Lettuce, Cabb., p. score, 6*d.* to 1*s.*
— Cos, per score, 6*d.* to 1*s.*
Celery, per bun., 2*d.* to 3*s.* 6*d.*
Mushrooms, per pottle, 2*d.* to 1*s.* 6*d.*
Small Salads, per punnet, 6*d.* to 2*s.*
Watercresses, per doz. bun. 3*d.* to 6*d.*
Parsley, per doz. bunches, 2*s.* to 4*s.*
Tarragon, Green, per bun. 6*d.* to 1*s.*
Radilye, per score, 1*s.* to 2*s.* 6*d.*
Green Mint, 4*d.* to 6*d.* per bunch
Marjoram, green, p. doz. bun. 1*s.* 6*d.* to 3*s.*
Cheryll, per punnet, 6*d.* to 8*d.*
Salsafy, per bundle, 1*s.* to 1*s.* 6*d.*
Scorzonera, per bundle, 1*s.* 6*d.*

HOPS, Friday, Feb. 9.

The Hop Market for some days past has been more quiet, but prices remain firm, as holders feel satisfied that, with the unusual small stock on hand, the least speculative demand or unfavourable symptom in coming crops would cause a very considerable advance on the present currency.

CAMBERWELL.—CAMDEN NURSERY GROUNDS.

MESSRS. ELLIS AND SON will SELL by AUCTION, on the above Premises, near Camden Chapel, Peckham-road, on Tuesday, the 13th of February, and following day at 11, on account of the number of lots, under distress for rent, the entire STOCK, Buildings, and Tools; consisting of two capital Greenhouses, 26 feet in length, heated by hot-water-pipes. Forcing pits, Cucumber and hand-lights, Shop fixtures, a case of 180 drawers labelled for seeds, and sundry tools. The stock includes an extensive assortment of standard and wall-fruit trees, a great variety of well-selected Roses, Geraniums, and Greenhouse plants, Fuchsias, Auriculas, Dahlias, Ipomœas, Myrtles, Camellias, American plants, Shrubs, and Evergreens, some good specimens of Ornamental trees, and fine Mulberries, a number of Gooseberry and Currant trees, various seeds, &c. To be viewed three days prior to the sale. Catalogues may be had on the premises; at the Horns, Kennington; of Messrs. Fairbairn, auctioneers, Clapham Rise; of Messrs. Forrest and Co. nurserymen, Kensington-road; and of Messrs. ELLIS and SON, auctioneers, 26, Fenchurch-street.

TO BE SOLD, about 2000 clean, robust, well-grown Succession QUEEN PINE PLANTS, from 2s. 6d., 3s. 6d., to 5s. per plant; those at 5s. will fruit this autumn, delivered free in London. Gentlemen in want of such will find this an advantageous opportunity of supplying themselves. Application to be made to Mr. RENMAN, Gentleman, 4, Great Russell-street, Covent-garden, or by card, at the Growers', Forest-hill, London.

NATURAL GRASSES, Separate or mixed.—Poa trivialis, P. pratensis, P. memoralis, P. fertilis, P. angustifolia, Festuca pratensis, F. duriuscula, F. ovina, F. rubra, F. elatior fertilis, F. gigantea, F. loliacea, Agrostis stolonifera, A. palustris, Dactylis glomerata, Cynosurus cristatus, Alopecurus pratensis, Anthoxanthum odoratum, Avena flavescens, A. pratensis, A. pubescens, Phleum pratense, Lolium perenne, L. perenne Russellianum.

The above, together with Perennial Clovers and other ARTIFICIAL and NATURAL GRASSES, may be had separate by name, or will be supplied in mixtures of such sorts, and in such proportions, as to suit the soil and situation for which they may be required. The cost of the seeds, this season, is from 30s. to 34s. per acre.

Messrs. SUTTON and SONS have for many years supplied Noblemen and Gentlemen with GRASS SEEDS for laying down permanent Pastures and mending old ones, and have the privilege of referring to estates in many parts of England, where the Proprietors have expressed themselves desirous of recommending Messrs. SUTTON'S Seeds.

The FINEST SORTS for LAWNS, mixed, Warranted free from Weeds, 4s. per Gal.; 30s. per Bush.—Reading Nursery, Berkshire.

MIXED GRASS SEEDS, FOR PERMANENT PASTURE AND LAWNS.

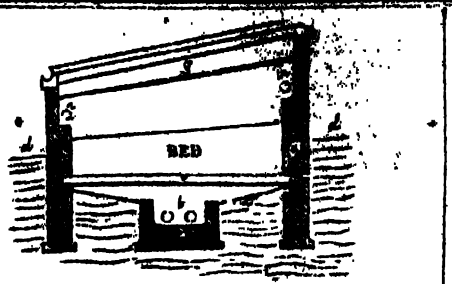
ROGER SMITHE, of Eastling, Faversham, Kent, has for Sale the above Seed at 8s. per bushel, three bushels per acre, containing all the best sorts, with a good proportion of the Clovers and Trefoils properly mixed for the generality of land. Persons are requested to name the soil, as the mixture will be regulated by that. Also all other Seeds proportionably low. These will be sent to any part of the Kingdom.

GARDEN VEGETABLE SEEDS.—A Selection of the best and most-approved kinds, in secure packages, for 40s., 20s., and 10s. each; sent carriage free to any part. Parties are at liberty to name distinctly what sorts they require.—Direct to J. and H. BROWN, Albion Nursery, Stoke Newington, London. A post-office order or reference is required. Superior Melon and Cucumber Seeds, 1s. 6d. per packet.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.



D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

GENDLE'S TANK SYSTEM OF HEATING.

STEPHENSON AND CO., 61, Gracechurch-street, London, Inventors of the IMPROVED CONICAL and DOUBLE CYLINDRICAL BOILERS, having been much engaged in heating buildings upon the above system with Tanks of various materials, solicit the attention of scientific Horticulturists to an Iron Tank now fitting up on their premises, which offers most decided advantages over every other article hitherto employed for the same purpose. These tanks, which are ornamental in appearance can be made from 10 to 100 feet long and of any width and depth, and can be connected or disconnected by any working Gardener without the slightest difficulty, thus affording the opportunity to persons in remote districts of employing this much approved method of heating without the assistance of Engineers. The Tanks can be applied to Boilers and Pipes already fixed, and from the present low price of iron will be found cheaper than of any other material. MR. RENDLE, of Plymouth, has kindly undertaken to receive orders and furnish information to any persons in his neighbourhood, and prices for any size will be forwarded upon application to S. and Co.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have now fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be patiently relied upon: they have put up one at the Horticultural Gardens, where it and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the conical pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melon-pits, &c. &c. The arrangement is such that any gentleman or gardener may have the whole constructed, so as to be put together with the greatest facility by the purchaser, first sending a correct plan to the Establishment. A Prospectus may be had [illegible]

J. WEEKS & Co., ARCHITECTS, HORTICULTURAL BUILDERS, and HOT-WATER APPARATUS MANUFACTURERS, Gloucester place, King's-road, Chelsea.

GENUINE PERUVIAN & BOLIVIAN GUANO ON SALE, BY THE IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
GIBBS, BRIGHT, AND CO., LIVERPOOL AND BRISTOL.
47, Lime-st., Jan. 31, 1844.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with synopsis of mode of use, on applications to MARK FOTHERGILL, 40, Upper Thames-street, London.

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine as imported.—Apply to COTESWORTH, POWELL, and PRYOR, London; EDWARDS, DANSON, and Co., Liverpool; or WILLIAM J. MYERS and Co., Liverpool, the Importers.

MANURE FOR GRASS, &c.—POTTER'S GUANO.
Testimonial of Lord Zetland, Dec. 2, 1842.

POTTER'S GUANO, 2 cwt. per acre, yielded of *Hay*	2 tons	8 cwt.
Peruvian Guano, 2 cwt. per acre, yielded of *Hay*	1 ,,	18 ,,
Difference in favour of Potter's Guano		10 cwt.

BEAUTIFUL FLOWERS.—POTTER'S CONCENTRATED LIQUID GUANO, in quart bottles, 1s. 9d. each, at the principal Chemists and Seedsmen in town and country.

"I used POTTER'S GUANO on my Pansies; they were *much larger* than I ever had them before, and remained in full blow longer than I ever recollect. JOHN RITSON, Sunderland."

"POTTER'S GUANO will convert your desert into a paradise."—Professor LINDLEY, in *Gardeners' Chronicle*, 1843, p. 560.

Works, 28, Upper Fore-street, Lambeth.

For further testimonials see this Paper of the 6th Jan., 1844.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7s. per cwt.

Phosphate of Potash	. . .	15s. per cwt.
,, Soda	. . .	12s. ,,
,, Magnesia	. . .	5s. ,,
,, Ammonia	. . .	1s. per lb.

THE URATE of the LONDON MANURE COMPANY, 5l. per Ton. It is with the greatest satisfaction after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURSER, Secretary, 40, New Bridge Street.

GLASS SUPERSEDED for HORTICULTURAL PURPOSES by WHITNEY'S CHEMICAL TRANSPARENT WATERPROOF COMPOSITION, rendering Muslin, Calico, or Linen, for the Frames of Greenhouses, Pine, Melon, or Cucumber Stoves, &c., impervious to rain or moisture, admitting light equal to Glass, much warmer, and the plants never burn under it.

Noblemen, Gentlemen, and Gardeners will, by using this composition have the only effectual protection for their Fruit-trees during the blooming season; it is a certain defence from frost, sleet, wind, and blight; its transparency admits the general beams of the sun, with abundance of light, which causes the bloom to expand with increased luxuriance, the fruit to set and swell more freely, much earlier, and a crop of fruit to any extent may be warranted. The covering not to be moved by day (except to thin the Fruit, which will be necessary), till the month of June. It is recommended that the Calico be prepared early, so as to be thoroughly dry before using.

Sold in Bottles, with directions for use, pints, 2s. 6d., quarts, 4s. 6d. each. One pint is sufficient to coat four Frames twice over, each Frame to be 5ft. by 2ft. 3in., or thereabouts. Prepared by GEORGE WHITNEY, Chemist, Shrewsbury. Seedsmen, Florists, and Merchants supplied by Mr. W. BAILEY, Chemist, North-street, Wolverhampton. Appointed Agents:—Messrs. BUTLER and MUCKLEY, Covent Garden, where a sample of prepared calico may be seen; Mr. WATKINSON, Market-place, Manchester; PAGE and Son, Southampton; T. and C. WHALLEY, Nurserymen, Liverpool.

Agents wanted for London and the country.

NETTING, BUNTING, and SCRIMS, for EFFECTUALLY PRESERVING the BLOSSOM of FRUIT-TREES from FROST, in convenient quantities and at small cost, at BENJAMIN EDGINGTON'S Marquee and Rick Cloth Manufactory, No. 2, Duke-street, Southwark; and 293, Piccadilly, London.

"We understand from some of our friendly horticultural acquaintance, that wherever Bunting Screens have been employed, the wall-fruit has set in the finest manner, hence we again recommend this fabric in preference to any other."—*Bell's New Weekly Messenger.*

N.B. Some of the canvas used at the Smithfield Club Cattle Show to be sold as second hand, at moderate price, suitable for Rick Cloths, &c.

HEATH-SOIL.—Numerous Gentlemen, visitors at Bournemouth, having applied to R. WHITE & Co. for supplies of the Fine Heath Peat Soil which abounds in that locality, they beg to inform them that they have now made arrangements to be allowed to remove the same, and can consequently offer it and the White Sand at 10s. 6d. per sugar hogshead delivered free on board a coasting vessel here.

Poole Nursery, Feb. 10, 1844.

Just ready, price 1d.

PRACTICAL HINTS to Practical Men, on NEW and OLD MANURES, by JOHN DODDRIDGE HUMPHREYS, Esq., author of the Electro-Physiology of Man, &c., &c. Full information is here given as to the advantages of the New Manure called HUMPHREY'S FARMER'S COMPOUND, which is not subject like the Guano to be washed out of the soil, but unites the progressive action of the natural with the highest fertilising powers of the best chemical agents. Wholesale Agents, DAVY, MACMURDO, and Co., 100, Upper Thames-street, London.

LONGMAN, BROWN, GREEN, and LONGMANS.

SCREENS for PROTECTING TREES in Blossom and Fruit from injuries by Wasps and Flies, and for shading Hothouses and Conservatories, Pines and Melons, Tulip-beds, &c., &c.

N. HULME, Paradise-Green, Knutsford, Cheshire, manufactures the following Articles:—Canvas Netting, of three different textures, at 1d.; of a stronger Quality, at 2d.; and of Yarn doubled, at 3d. per square yard. Woollen Netting of different sorts, at 5d., 7d., and 10d. per square yard. The above articles are made from one to four yards in width, as may suit the purchasers.—N. H. has for many years had the honour to supply the Nobility, Gentry, and others, in various parts of the Kingdom with the above articles, and has had the happiness to give general satisfaction.

N.B.—Patterns, with the prices annexed, sent (if desired), to any persons wishing to become purchasers. In case of Orders to the amount of five pounds or upwards, carriage by canal or railway will be paid to London, or any place not more distant.

MARDER'S GRAFTING COMPOSITION.—From the expansive and adhesive properties of this Paste, it neither retards the progress of the swelling, nor admits the air, moisture, or frost in the process of healing the Graft, thereby insuring a remedy against failures so prevalent from the adoption of the present imperfect, dirty, and troublesome mode. Sample pots, with directions, at 1s. 6d. and 2s. 6d., sufficient for 100 and 200 Grafts, may be had of the wholesale Agent, Mr. RIPLEY, Hooker's-court, Nicholas-lane, London; VARWELL & SON, Exeter, and of the Proprietor, Lyme Regis. Six small or four large pots will be forwarded to any part of the Kingdom free of carriage, on receipt of a Post-office order to Mr. RIPLEY, or to the Proprietor.

PROFITABLE MANUFACTURE FOR LANDS, &c.

THE PATENTEE of a Clean and Excellent PREPARATION for Fields and Garden Crops, is ready to grant LICENCES, and to supply Skilful Workmen; also ample Instructions for Manufacture and Use. Seedsmen and others connected with Farmers may thus realise a good income from small Capital, without risk; Landlords could soon make their lands fertile.

TERMS.—A Premium of Two to Three Hundred Pounds, according to the extent of district exclusively secured. Undoubted reference will be given.

Address, post-paid, To Chymists—care of Mr. ARNOLD, 12, Curzon-street, May-fair, London.

GRAINS TO LET.—Three Nails of Grains per week to Let, about 12 quarters each Malt. Hay, Straw, Chaff, &c., would be taken in exchange.—Apply to Messrs. STAUNTON'S, No. 9, Strand.

CUCUMBER and MELON BOXES and LIGHTS.—For Sale, one, two, and three-light BOXES and LIGHTS, of all sizes, ready for immediate use, warranted of the best materials, packed and sent to all parts of the Kingdom; two-light Boxes and Lights complete from 1l. 5s. Garden Lights made, glazed, and painted, from 1s. per foot. Sashes and Frames made, glazed, and hung complete, 1s. 8d. per foot.—At JAMES WATES' Sash Manufactory, 9, Clarement-place, Old Kent-road.

*** References given.

On January the 8th, 1844, will be published, handsomely printed in Demy 8vo., Part the First, Price 12s.,

SPECIES FILICUM; OR A SYNOPSIS OF ALL KNOWN FERNS. This first Part contains the ENUMERATION of POLYPODIACEÆ in part, and PLATES 1. to XX. By Sir WILLIAM JACKSON HOOKER, K.H., LL.D., F.R.S., &c., &c., Vice President of the Linnean Society, and Director of the Royal Botanic Garden at Kew.

*** It is intended to publish Part the Second on the 1st March, 1844.

London: WILLIAM PAMPLIN, 45, Frith-street, Soho-square.

CURTIS'S BOTANICAL MAGAZINE.—Just published, price 3s. 6d. coloured, No. 208 of the NEW SERIES of this interesting and scientific work, edited by Sir William Jackson Hooker. It contains beautifully coloured figures of Cereus Extensus—Dracæna Poly bulbon—Ipomœa crassipes—Erica Stanoniana—Tetranema Mexicanum—Scaphyglottis violacea. The above work has been published monthly, without any intermission, for the last fifty-eight years, and stands unrivalled by any other botanical publication in beauty and extent. The whole or any part of the work from its commencement may be had of Mr. SAMUEL CURTIS, at the Botanical Magazine Warehouse, Glasshouse-wood, near Braintree, Essex.

SUPPLEMENT TO THE ENGLISH BOTANY.—No. 38 was Published on the 1st of January, and No. 39 on the 1st of February. Messrs. Complete, in cloth, price 10s.; or in Nine Numbers, price 1s. each,

THE HORSE: its History, Races, Structure, Diseases, and Treatment. By W. YOUATT. With a Treatise on Draught. A New and Enlarged Edition, re-written, and brought down to the present state of Veterinary Science. With an entirely New Set of Cuts, drawn by HARVEY.

CHARMAN & HALL, 186, Strand.

NEW METHOD OF TRANSPLANTING.

On Thursday next, 8vo., with an Illustrative Plate,

THE TREE-LIFTER; or, a New Method of Transplanting Trees. By Colonel GEORGE GREENWOOD, London: LONGMAN, BROWN, GREEN, and LONGMANS.

BOOKS RECENTLY PUBLISHED, OR IN THE PROGRESS OF PUBLICATION.

ENCYCLOPÆDIA BRITANNICA; Seventh Edition, Edited by Professor NAPIER. Now complete in 21 Volumes 4to; illustrated by 606 Engravings on Steel and many Thousands on Wood.

In Literary Execution, and Embellishment, as well as in the Literary Value of its contents, the Work is accommodated to the highest taste and advanced information of the times; and, whether for the purpose of systematic study or occasional reference, the Proprietors are satisfied that the Seventh Edition of the ENCYCLOPÆDIA BRITANNICA will be found to be the most valuable addition which can be made to a modern library.

A recent writer in the CHAMBERS'S EDINBURGH REVIEW, in adverting to the pre-eminent value of this Encyclopædia, observes, that, "*An Australian or New Zealand settler, who left his home with no other accomplishment but that of being able to read, write, and count, might, with such a companion, beguile his long and weary voyage, and become a well-informed man before he reached his destination.*"

Lord BROUGHAM also, in his recent speech on the Copyright Bill, observed, "*If any work was not only valuable and useful, but absolutely necessary for the country, it was this.*"

An Index of 60,000 references, compiled with great industry and judgment, is appended to the work; forming a ready key to its multifarious contents.

TRAVELS through the ALPS of SAVOY, and OTHER PARTS of the PENNINE CHAIN, with Observations on the Phenomena of Glaciers. By JAMES D FORBES, F R S., Sec. R.S E., Corresponding Member of the Royal Institute of France, and Professor of Natural Philosophy in the University of Edinburgh. In a handsome volume, imperial 8vo. Illustrated by a large Map of the Mer de Glace of Chamouni, Lithographed Views and Plans, and Engravings on Wood, price 28*s.*, or, with the large Map, coloured, in a case, 31*s.* 6*d.*

"A volume full of interesting and novel scientific information, pleasant and readable"—*Athenæum.*

A VOYAGE ROUND the COASTS of SCOTLAND and the ISLES. By JAMES L. WILSON, F.R.S.E., M W.S., &c. With a Map of Scotland, exhibiting the Tract of the Voyage, a Chart of St. Kilda; 20 Etchings on Steel, by Charles H. Wilson, A R S.A., from Sketches during the Voyage by Sir Thomas Dick Lauder, Bart., and numerous Wood Engravings from the same Sketches, drawn by Montague Stanley, Prior, and Sargent, and Engraved by Branston, Landells, and other Artists. 2 vols. post 8vo. Price 21*s.*

"Two of the most charming volumes we have had under our notice for a long time They describe scenery round which the imagination loves to linger, and of which no description can be fatiguing"—*Court Journal.*

"Written in a flowing and animated style * * * Those who wish to know Scotland in its coasts and islands will derive from this work both instruction and pleasure; those who desire to know the value of their country and its institutions, as shown even in the most inaccessible parts of its remotest provinces, will ponder over its contents, and the general reader, who seeks only for that rational amusement which the personal narrative of a lively and intelligent tourist never fails to yield, will find it in these volumes."—*Edinburgh Review.*

BLACK'S GENERAL ATLAS OF THE WORLD. New Edition. To be completed in Eight Parts, (Price 6*s.* each,) of which Seven are now Published.

This Atlas, which is already favourably known by the large circulation of the former Edition, is unsurpassed either in accuracy or beauty of execution by any work of its class, while in cheapness it is altogether unequalled It contains 67 Folio Maps, engraved on Steel in the first style of Art, by SIDNEY HALL, HUGHES, and others, with Geographical Illustrations, Statistical Tables, and *an Index of all the names occurring in the several Maps, amounting to nearly 60,000*, with their Latitude and Longitude, and the Number of the Map in which they will be found.

The present Edition has been revised and corrected throughout, and many important New Maps have been added to it. Part VII.—which alone is required to complete the work—will contain the General Index, and will appear early in March Part VIII., containing the New Maps, is Just Published, and is recommended to the purchasers of the former Edition.

"We may now say, with certainty, that as no Atlas exceeds Black's in the neatness of its form and the utility of its dimensions, so, in Geographical accuracy, and beauty of execution, it equals any work extant of similar pretensions, and yet greater charge We have not been disappointed in a single reference to any of the Maps yet issued, and we have severely tested those of the present Number."—*Atlas.*

A DICTIONARY OF MEDICINE FOR POPULAR USE; containing an Account of Diseases and their Treatment, including those most frequent in warm climates; with Directions for Administering Medicines; the Regulation of Diet and Regimen; and the Management of the Diseases of Women and Children By ALEXANDER MACAULAY, M D., Fellow of the Royal College of Surgeons of Edinburgh, and Physician-Accoucheur to the New Town Dispensary. *Eighth Edition.* 1 vol. 8vo. double columns. 14*s.*

"Just such a Work as every head of a family ought to have on his book shelf."—*Brighton Herald*

"If sterling merit be the passport to success, this work will obtain the most extensive celebrity"—*Bath Herald.*

"Calculated to accomplish all that could be wished in a popular system of medicine"—*Edinburgh Medical and Surgical Journal.*

"We have been nothing of the kind better adapted for consultation"—*Literary Gazette*

"Decidedly the most useful book of the kind that has yet been offered to the public"—*Caledonian Mercury.*

ANGLO-CATHOLICISM NOT APOSTOLICAL; being an Inquiry into the Scriptural Authority of the Leading doctrines advocated in "The Tracts for the Times," and other Publications of the Anglo-Catholic School. By W. LINDSAY ALEXANDER, M.A., Author of "The Connexion and Harmony of the Old and New Testaments," &c. 1 vol. 8vo. Price 6*s.*

"Mr Lindsay Alexander's learned and able work"—*Edinburgh Review*

"It is written in a calm considerate spirit, and states the arguments of opponents with fairness and candour"—*Athenæum*

"We most cordially recommend this book It is not so short as to be superficial nor so long as to be tedious It does not bewilder the reader by wandering over the almost interminable range of topics which might be brought into this controversy, but judiciously confines attention to those leading questions which only are of real moment, and which are fundamental to the rest The style of the work is simple and appropriate, serious as befits the grave subjects it discusses, clear and graceful as that of one accustomed to orderly thinking, and well practised in the communication of his thoughts to others"—*Eclectic Review.*

"We like the manifested a most conciliatory and Christian spirit in his management of the argument."—*Church of England Quarterly Review.*

THE FRUIT, FLOWER, and KITCHEN GARDEN. Forming the Article "HORTICULTURE," in the Seventh Edition of the ENCYCLOPÆDIA BRITANNICA. By PATRICK NEILL, LL.D., F.R.S.E., Secretary to the Caledonian Horticultural Society. In post 8vo, illustrated with upwards of Sixty Woodcuts. Price 6*s.*

"One of the best modern books on Gardening extant, clear, comprehensive, and in every part well reasoned."—*Loudon's Gardener's Magazine*

"No country gentleman who takes an interest in the appearance and successful management of his policies should neglect to furnish a copy of this work to his gardener's library."—*Perthshire Courier.*

"A hand-book of practical instruction in the art superior to any that has hitherto appeared, and which no one with a garden ought to be without."—*Caledonian Mercury.*

"The best book of the kind"—*Nottingham Journal.*

"It includes all the improvements which [illegible] has introduced"—*Northampton Mercury.*

"A perfect guide in every department of [illegible]"—*Berwick Courier*

"The first really practical treatise on Horticulture we have seen."—*Somerset County Gazette.*

ADAM AND CHARLES BLACK, EDINBURGH; LONGMAN and Co.; SIMPKIN, MARSHALL, and Co.; WHITTAKER and Co.; and HAMILTON, ADAMS, and Co., London; and JOHN CUMMING, Dublin.

WORKS

On AGRICULTURE, LAND-SURVEYING, NATURAL HISTORY, & SCIENCE.

PUBLISHED BY

LONGMAN, BROWN, GREEN, & LONGMANS.

AN ENCYCLOPÆDIA of AGRICULTURE; comprising its History in all Countries, the Principles on which Agricultural Operations depend, and their Applications to the Farming of Britain and similar Climates By J. C. LOUDON, F.L.S. Third Edition, 8vo, nearly 1,300 Woodcuts, 2*l.* 10*s.*

THE FARMER'S ENCYCLOPÆDIA, and DICTIONARY of RURAL AFFAIRS; embracing all the recent Discoveries in Agricultural Chemistry, adapted to the comprehension of unscientific readers By CUTHBERT W. JOHNSON, Esq., F R S. 8vo, Woodcuts of the best and most improved Agricultural Implements, 2*l* 10*s*

ELEMENTS of PRACTICAL AGRICULTURE. By DAVID LOW, Esq., F R.S E., Prof of Agriculture in the University of Edinburgh Fourth Edition, greatly improved. 8vo, 200 woodcuts, 21*s*

JOHN CATTELL, Seed and Nurseryman, Westerham, Kent, begs to call the attention of the Public to his Superior Stock of Seeds, Trees, and Plants. Separate Catalogues of which are now ready. Standard and Dwarf Pansies remarkably fine, Bedded plants of the newest and best sorts of Strawberries. A good stock of the New Improved Autumn Raspberry, "Rodger's Victoria," warranted true at 3*s*. 6*d*. per dozen, etc. per 100. A few good plants of Veronica speciosa. Seeds carefully packed for exportation.

J. C. is in want of a few hundreds of seedling Azalea pontica, single stemmed plants, about the size of a common pen-quill, a plant or two of which as sample, may be forwarded, with price and quantity per Post.

NEW DAHLIA, "SYRED'S HERO or MAIDA."—Colour, bright orange; well cupped, and very constant, strong robust habit, adapted for a back-row flower; and where colour is predominant in clump-showing it is superior to any orange yet out. Having been raised by an Amateur it was only exhibited for competition at Hammersmith, where it obtained the first Seedling prize, and at Stockwell Seedling Show, where it also obtained a prize.

Daniel Syred, Nurseryman, Richmond-road, Maida-hill, Paddington, having purchased the stock of the above fine Dahlia, has but a few strong roots left for sale, at 21*s*. each, and strong pegcuttings at 10*s*. 6*d*. each. Plants [illegible] May. 10*s*. 6*d*. each. The usual discount to the Trade. No objection to exchange roots or plants for any approved variety.—London, Feb. 16, 1844.

R. WHITE & Co.'s Collection of Plants, of which a Catalogue is now ready, comprise every variety of Geranium, Fuchsia, Verbena, Chrysanthemum, Dahlia, &c. which is worthy of cultivation. The following collections are offered, the selection being left to the purchaser —

			£	s.	d.
40	first-rate varieties of	Geranium	5	0	0
20	" "	do	3	0	0
12	" "	New do.	3	0	0
20	" "	Fuchsia	1	1	0
40	" "	Chrysanthemum	1	1	0
20	" "	Verbena, including Seedlings which were submitted to Dr. Lindley for his opinion, and reported to be "all very fine," see *Gardeners' Chronicle*, Sept. 30th and Oct. 7th "*Alfred*. All your Seedling Verbenas are good flowers"	1	1	0
12	first-rate Dahlias		1	1	0
100	fine show do.		2	10	0

The above will be ready for delivery in strong plants the first weeks of April and May, and orders containing remittances will be executed in strict priority. Orders amounting to 5*l*. will be delivered free

Agents for the sale of Stephenson's Conical Boiler, Tank, &c, which may be seen at work, and can be supplied at Manufacturers' prices. Also Whitney's Composition Substitute for Glass —Poole Nursery.

NEW AND SUPERB COLLECTION OF SEEDLING FUCHSIAS.

W. J. EPPS begs to announce that he purposes sending out, on the first week in March, Ten Magnificent Seedling Fuchsias, which have merited high opinions from the most distinguished judges of the day. They are very distinct, and possess the finest properties of any Fuchsias yet known

BRIDEGROOM (Epps').—A fine flower, of great size and splendour, light pink tube, sepals very smooth and rich, beautifully tipped with green, corolla very large, of a deep vermilion colour, very like Chandleri, but twice the size, of a splendid erect habit, and a very free bloomer.—(This was submitted to the Editor of the *Florist's Journal* in November last. See Answers to Correspondents Price 5*s*

ESPARTERO (Epps').—This flower is of large size, tube long, bright scarlet, short sepals, expanding well, and exhibiting an extraordinary large deep rich rosy-purple corolla, immense bloomer, and a very distinct variety —(See Mr Ayres' opinion, *Gardeners' Chronicle, Nov 25, 1843*, on the article of Fuchsias. Price 7*s* 6*d*.

KENTISH HERO.—*A fine flower*, of a beautiful vermilion red tube, and sepals well expanded, exhibiting a splendid puce purple corolla of great substance, very distinct, fine compact habit Price 5*s*.

DUKE OF WELLINGTON — *In immense flower*, of great substance, very rich rosy pink tube, and sepals beautifully smooth and slightly tipped with green, very large corolla, of a rich rosy crimson, sepals expand well, almost reflex, fine free habit Price 5*s*

WINSEMII.—(Professor Lindley's opinion, see *Gardeners' Chronicle, Aug. 5, 1843*, to Correspondent, *J. W., Tenterden.*) Price 5*s*.

"No 1, tube long and smooth, of a rosy crimson, sepals open very wide, with the points slightly tipped with green, corolla short, of a rosy vermilion colour; *a fine variety*"—Professor Lindley

MARIA.—"No 2, tube and sepals rose coloured and smooth, corolla large, of a fine bright blue purple; *an elegant variety*"—Professor Lindley. Price 5*s*.

FLORENCE.—"No 6, tube smooth, sepals spreading, rosy in colour, with the points slightly tipped with green, corolla rosy purple, *very pretty flower*"—Professor Lindley Price 5*s*.

"All these seedlings are good in form, bright in colour, and smooth in texture"—Professor Lindley.

KENTISH BRIDE.—This magnificent flower was raised by H. Busby, gardener to T. L. Hodges, Esq., Hemsted, Kent, and has merited the high opinion of Professor Lindley, Editor of the *Gardeners' Chronicle*, Mr G. Glenny, Editor of the *Gardeners' Gazette*, and Mr. Ayres, the able writer on the Amateur's Garden. Price 7*s* 6*d*

Professor Lindley's opinion, see *Gardeners' Chron.*, July, 8, 1843, to correspondent, *H B*—"Your best seedling fuchsia is No. 4. This is a beautiful variety, seed-vessels bright green, tube and sepals bright rosy scarlet, corolla large, of a bright violet purple. It is a well proportioned flower"

Mr. Ayres' opinion, see *Gardeners' Chronicle*, Nov. 25, 1843.

Mr. G Glenny's opinion, see *Gardeners' Gazette*, Oct 21, 1843, to correspondent, W J E—Fuchsia,—"Pink sepals, rich purple corolla, long footstalk If the habit of the plant be as good as the flower, it is an acquisition.'

The habit of this plant is very compact, and of a beautiful rich green glossy foliage, and with its rich pink tube, sepals, and blue purple velvet corolla, forms a lovely object

EMPEROR OF CHINA.—This is a fine flowe raised by the same person as Kentish Bride, and submitted to Professor Lindley at the same time. Price 5*s* "No 1, which is smaller to No 2, and having a stout tube. This is a fine flower, with less blue in the corolla."—Professor Lindley.

PRINCE OF WALES.—This also was raised by H. Busby, and submitted to Professor Lindley with two others. *An immense Bloomer*. Price 5*s* "No. 3 is a stout flower of a good colour, with long sepals, which expand freely and expose the corolla, which is of a rosy purple."—Professor Lindley.

*** The Collection, Two Guineas and a half. A remittance from unknown Correspondents. The usual allowance to the Trade where two or more plants are taken.

Bower Nursery, Maidstone, *Feb. 1st*, 1844

GAINES'S NEW AND FIRST-RATE PELARGONIUMS now ready for delivery, in strong, healthy Plants. The following are a few selected:—Gaines's Elegans nova, King of Beauties, Ackbar, Lady Prudhoe, Saxon King, Excelsa, Beauty Supreme, Mogul, Edith, Countess of Zetland, Cotherstone, Egbert. A list of Pelargoniums, Pansies, Calceolarias, Fuchsias, Verbenas, Auriculas, Cinerarias, Chrysanthemums, Dahlias, &c., which contains many new Seedlings of first-rate qualities; plants in May, 10*s*. 6*d*.; also a few roots of his Seedling Dahlias Princess Alice and Twickenham Rival are still to be disposed of at the Nursery, Surrey-lane, Battersea.

H. MAJOR, Knosthorpe, near Leeds, begs to say that a descriptive List of his New Shrubby CALCEOLARIAS, together with a select List of PANSIES and DAHLIAS, is now ready, and may be had on postpaid application. Mr. M. offers the whole on terms worthy the notice of his friends.

A few packets of select Pansy Seed, saved from sorts possessing well-marked eyes, may be had at 2*s*. 6*d*. per packet. Small packets of very select Calceolaria Seed, saved from Mr. M.'s own seedlings, 2*s*. 6*d*. per packet.

DANE CROFT NURSERY, STOWMARKET, SUFFOLK.

SAMUEL GIRLING, English and Foreign Florists, in returning their sincere thanks for the liberal patronage they have hitherto enjoyed from the Nobility, Gentry, and Public at large, both in this Country, England, and Ireland, beg respectfully to intimate that they have received their Full Supply of SEEDS, in fine condition, for SPRING SOWING, of first rate quality.

From the arrangements they have recently made with some of the first Growers, their Customers may depend on receiving Fresh Seeds of all descriptions, carefully selected for J. D. and Sons' Sales.

J. D. & Sons beg to call the attention of their Friends to their Stock of EVERGREENS, FRUIT and FOREST TREES, in their Nurseries of Inverleith and Broughton Park, which will be found equal in quality and extent to any in Scotland.

J. D. & Sons beg further respectfully to intimate that they have considerably extended the Floral Branch of their Business, and they assure their numerous Customers and the Public at large that no pains or expense will be spared by which the efficiency of every department of the concern shall be secured, so as to ensure a first-rate article at the lowest figure.

Catalogues of every article connected with their trade have just been published, and can be forwarded, per post, on the receipt of postage stamps to the amount of sixpence.

N.B.—Noblemen and Gentlemen provided with experienced Gardeners, Land Stewards, and Wood Foresters, whose character and abilities may be depended on.—82, South Hanover Street, Edinburgh, February 16, 1844

GENUINE BEECHWOOD MELON SEED.

R. GLENDINNING respectfully begs to inform the Cultivators of the MELON that he has had presented to him by Sir John S. Sebright, Bart, Seeds of the true variety of his delicious MELON, for besides being one of the very best sorts known, it is of easy cultivation and a good bearer. This opportunity will enable gentlemen to procure it *quite genuine*, which is rarely the case, as the following note will testify.—

"Beechwood, Feb. 5, 1844.

"Sir,—I send you a small parcel of the Beechwood Melon Seed. None that I have seen exhibited under that name, nor any that I have seen grown from seed that has been bought, are of the true sort, but have obviously been intermixed with other varieties. I have grown no other for many years.

"Your obedient servant,

"To Mr. Glendinning "J. S. Sebright."

R. G. has also a few seeds of the true SION FREE-BEARING CUCUMBER, a splendid variety which has been nearly lost.

Packets of the above sent by post free.

Beechwood Melon, per packet . . . . 5*s*.
Sion Tree bearing Cucumber, per packet . 5*s*.

R. G.'s Kitchen garden and Flower-Seeds have been selected with great care, and embrace all the new and good kinds.

Chiswick Nursery, near London, Feb. 16, 1844.

JOHN MILLER, surviving Partner of the late firm of Swinney & Miller, Nursery and Seedsmen, Bristol, begs respectfully to [illegible] Nurserymen, the Trade, and his Friends in general, that he has commenced business as Auctioneer and Valuer of Horticultural and Agricultural Stock, &c., and hopes by strict attention to the interest of his employers, to merit their support. Letters addressed to John Miller, Portland House, Kingsdown, Bristol, will meet with immediate attention.—Bristol, February 16, 1844.

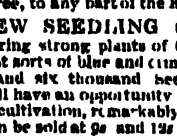
TO GENTLEMEN PLANTING.

J. AND J. FAIRBAIRN are induced from the uncertainty upon which they hold the Manor-street Nursery (situated contiguous to the Rhine Nursery, Clapham Rise, where attention will be given to all applications), to effect a sale of the Stock at as early a period as possible, consequently beg to solicit the attention of Gentlemen and the trade to the large and remarkably healthy and well-grown stock, consisting of fine large Laurels, twice transplanted, of extra growth; Portugal Laurels, very handsome; Silver Hollies, of various sizes; Evergreen Privets, fine Standard and Dwarf Roses in great variety, fine standard flowering Thorns, Almonds, Æsculus, Robinias, and other Ornamental Trees, and Evergreen and flowering Shrubs, with a large stock of fine standard and dwarf, trained and unclipped Peaches, Nectarines, Apples, Pears, Plums, and Cherries, of the most approved kinds, and of growth rarely equalled; also, a large assortment of Forest Trees, consisting of Limes, Elms, Birch, Beech, Hornbeam, Spanish and Horse Chesnuts, Mountain Ash, Poplars, and Spruce, and Scotch Firs, also a large number of Gooseberries and Currants, of excellent growth, and of the best varieties in cultivation, to all of which J. & J. F. respectfully invite the inspection of Gentlemen and Nurserymen, flattering themselves that the general character of the stock is such as to ensure unqualified satisfaction, and which they are disposed to offer at very moderate prices for cash.

J. & J. F. respectfully beg to call the attention of Gentlemen to their advertisement of Heaths, &c., which appeared in the *Gardeners' Chronicle*, Oct. 21 and 28.

Nurseries, Clapham, near London Feb. 15, 1844

NEW HARDY ANNUAL



VISCARIA OCULATA—DARK-EYED VISCARIA.

T. AND J. BACKHOUSE, NURSERY AND SEEDSMEN, York, have the pleasure of offering to the Public the above new and beautiful Annual, which is figured at page 51, (No. 10), of the 'Botanical Register' for 1843. The blossoms are of a bright rose colour, with a deep crimson eye, and change to a pale purple. It flowers very abundantly through the greater part of the summer and autumn. It is a native of Algiers and may be sown either in the open ground in spring, or raised on pots and planted out.

Packets, 2s 6d each, will be sent, on the receipt of a Post office order, postage free, to any part of the Kingdom.

SPLENDID NEW SEEDLING CINERARIAS.—Fine early-flowering strong plants of CINERARIAS, saved from the very choicest sorts of blue and crimson colours, selected from between five and six thousand seedlings of last year. Those purchasing will have an opportunity of flowering some of the choicest sorts in cultivation, remarkably healthy, and having a large stock they can be sold at 9s and 12s per dozen, carefully packed for any part of the country. Applications including Post office orders will be immediately executed. Large bunches of SIBERIAN VIOLETS in full flower fit for potting, 6s and 9s per doz.—Direct to MICHAEL BREWER, Sen., Cambridge Nursery.

GREAT YARMOUTH NURSERY, NORFOLK.—1844.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS MAJESTY THE KING OF THE BELGIANS, and NURSERYMEN and FLORISTS by Special Appointment to HER MAJESTY THE QUEEN DOWAGER.

A SELECT CATALOGUE of the Newest and very best varieties of FUCHSIAS, VERBENAS, PETUNIAS, and ANAGALLIS, offered by YOUELL & Co.

YOUELL & Co., in submitting their Catalogue of Fuchsias for 1844, take the present opportunity of drawing the attention of admirers of the above elegant tribe of Plants, to their select and superb Collection. They have spared no expense in forming a Selection of such as are really good, to the exclusion of many that are mere nominal varieties; and they would refer to the numerous testimonials of success which attended their mode of selection last season, collections for Amateurs, for competition at the various Horticultural Exhibitions throughout the Kingdom.

YOUELL and Co. being the parties who first sent out per post, with safety, these tribes of Plants, are desirous of calling attention to their advantageous method of executing orders, namely, that they will deliver them free of postage (on the receipt of a post-office order), to any part of the United Kingdom, upon the following terms —

12 Extra Fine Vars.	12s	the Selection left to YOUELL & Co.
12 Ditto do.	21s	the Selection left to the Purchaser
30 Fine Varieties	40s	the Selection left to YOUELL & Co.
50 Extra Fine ditto	60s	the Selection left to the Purchaser

[With the exception of those marked thus *]

The Plants will be strong and healthy, and ready for delivery by the latter end of March, with the exception of those marked thus* (which will be ready in April), thus ensuring to the Purchaser fine Plants for competition in the ensuing season. Many of the Varieties can be supplied now.

NEW AND SPLENDID SEEDLING FUCHSIAS

* "FUCHSIA LOWRYANA." This brilliant Fuchsia, the entire Stock of which is in the possession of YOUELL and Co., is now for the first time offered to the notice of the Public.

Its exceeding large Tube and Sepals are of the most vivid Vermilion and excessively expansive, surpassing in brilliancy any variety that has yet been raised. It was exhibited at the London Horticultural Society's Meeting, Regent Street, and greatly admired, and was pronounced by all who saw YOUELL and Co.'s specimen plant, to be the most dazzling object of this tribe they ever witnessed. The foliage and habit exceedingly fine, a most abundant bloomer, and will be found a desideratum to every collection. Plants will be ready for delivery by the first week in April, at 7s 6d per plant. Usual discount to the trade, when not less than six plants are ordered.

YOUELL & CO., in calling the notice of Amateurs and others to the following seedling Fuchsias, raised in their Nursery, beg to state, that in the summer of 1843 they have paid very great attention to hybridising the best varieties in cultivation, from which they succeeded in raising upwards of 3000 plants, to the flowering of which one house was entirely devoted last year. And although many varieties, possessing superior claims to the attention of those cultivating this elegant tribe, were submitted for the opinion of D. Lowry, and most favourably noticed, yet Youell and Co. feel that in making a selection of the following six varieties, to which a most accurate description is affixed, will prove not only satisfactory to the purchaser, but to themselves.

These will be ready for delivery in April next, and as the stock is very limited early orders are solicited.

* "QUEEN VICTORIA." Tube and sepals smooth, of a bright vermillion; corolla stout, long of a fine purple rose-colour, forming a grand contrast, and of fine texture. Price 7s 6d. per plant.

* "PRINCE OF WALES." Tube and sepals rosy vermillion, the latter tipped with green, expanding well, and showing a fine corolla of rich rich purple. Price 7s 6d per plant.

* "PRINCESS ROYAL." Tube and sepals bright red; corolla large and exceedingly bright in colour. Price 5s. per plant.

* "MARCHIONESS OF NORMANBY." This is a large and showy flower, increasing four inches from the commencement of the pod to the termination of the pistil; tube and sepals scarlet; corolla stout, having a tinge of purple on it. 7s. 6d. per plant.

* "LADY ADELA PAUL." A flower of good form and substance; fine rosy red tube and sepals, the latter terminating in a decided green; corolla very large and stout, of a beautiful crimson purple. Price 5s. per plant.

* "LADY WATERMAN." Tube and sepals smooth, of a rosy vermilion, the latter turn up and expose the whole of the corolla, which is stout, and of a fine purple crimson. Price 5s. per plant.

When the six are ordered, they will be charged 1l. 11s. 6d. the set.

[With every other new variety worthy of cultivation, that may be advertised by other parties after the publication of this list.]

YOUELL & Co are preparing a short Treatise upon their successful mode of Cultivating the Fuchsia, and will be presented *Gratis* to Purchasers.

VERBENAS

* "MONARCH," (Youell's). Is a delicate creamy white, surpassing in its size and fragrance every other variety, the tufts of bloom measuring from 14 to 16 inches diameter, and will be sure to give satisfaction. Price 5s per plant.

* "BRILLIANT," (Youell's). This fine variety is of the most vivid scarlet, equal in this respect to "Melindris," the bloom, however, is three times the size, and very fragrant, and will prove most desirable in any collection. Price 3s 6d per plant.

* "PEPOAS," (Youell's). Is a most interesting variety, being a delicate lilac, with a distinct white eye, flower large and fragrant. Price 3s 6d per plant.

* "SURPRISE," (Youell's). Can be recommended, being a variety completely novel, and one that must be cultivated in every collection, the colour being of the richest rosy crimson, or ruby, producing tufts of flowers of 3½ inches in diameter, and delightfully fragrant. Price 1s per plant.

The above four varieties have been selected from upwards of two thousand seedlings, and may be confidently relied upon as possessing superior claims and will be sure to give satisfaction, will be ready to send out in April next, (post free). If the four varieties are taken, they will be charged 15s the set.

YOUELL'S TOBOLSK RHUBARB, TWO SPLENDID SEEDLING PICOTEES, FINEST CARNATIONS AND PICOTEES,

All of which are now ready for sending out.

ARAUCARIA IMBRICATA.

YOUELL AND CO., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms —Fine robust 4 year-old plants, 9 to 10 inches high, 10s. per 100, or 20s per dozen.

Fine Plants of CEDRUS DEODARA 2 ft. to 2ft. 6 ins., 10s. 6d. each.

FUCHSIA SEED.

YOUELL AND CO. beg to inform their Friends and the Public they have succeeded in saving a small quantity of the above from the very newest and best varieties, which they offer upon the following terms; —

A packet containing 100 seeds	10s.	
Do. do.	50 do.	5s.

Sent Post Free on the receipt of a Post office order. Directions for sowing, &c will accompany each packet.

This will form an admirable opportunity to those who intend competing for Seedling Prizes at the exhibitions of the present year. The quantities being very limited, early application will be necessary.—Great Yarmouth Nursery, Feb 6, 1844.

JOHN HANCOCK AND SON, NURSERYMEN, Durham, beg to call the attention of their friends to the following, of which they can supply plants of fine quality: —

"FUCHSIA LOWRYII," which they sent out in a very limited number in the autumn, in consequence of not being able to supply the orders received. They beg to submit the following extract, abridged from the Gardening article of the *Sunderland Times* newspaper —

"We have seen Fuchsia Lowryii a few days ago, and were much struck with the beauty of its general habit, profusion, rich, and elegant blooms. If it has one property more to be commended than another, it is its very bright colours, which are as rich as it is possible to conceive, and very vivid. Its foliage resembles Globosa, only prettier; it blooms freely on small plants distinct from the foliage. The flowers are much larger than any of the older varieties, the tube and sepals are of a fine clear crimson; which open freely, and reflex so as to display the whole of the large corolla, which is of a very bright dark blue, tinged towards the bottom to a deep purple; it cannot fail to be a general favourite with the admirers of the Fuchsia."

J. H. & Son feel confident that this will prove one of the finest varieties ever sent out. Strong Plants will be sent by post at 7s 6d each, carefully packed in tin cases.

FUCHSIAS Brockmanii, Balloonifiora, Cormackii, Champion (Smith's), Britannia (Smith's), Defiance (Smith's), Exoniensis, Eppsii, Deanniana, Fairy Queen, Gem (Ivery's), Ivoryana, Lancii, majestica multiflora (Knight's), multiflora coccinea (Knight's), majestica (Smith's), nobilissima (Smith's), Paragon (Smith's), Rogersiana, St Clare, Stanwelliana, Swalesii, Toddiana. Fine strong healthy Plants will be ready by 1st March, and can be sent by post if the plants are not required to be too large.

GERANIUMS —Constellation (Garth's), Count D'Orsay (Wilson's), Duchess of Sutherland (Gaines'), Lady Webster (Deverell's), Northern Beauty (Hancock's, fine), Nestor (Foster's), Oberon (Hodges'), Prince of Wales (Gaines'), Sir R. Peel (Foster's), Sunrise Lyne's), Beauty of Essex (Wilson's), at 10s, 6d. each; Rising Sun, Queen of the Fairies, Wonder (Garth's), Vanguard (Gaines'), at 9s each. Fine plants of the above, at 2l. 10s. per doz. Anna (Wilson), Alice Gray (Wilson's), Camilla (Wilson's), Duchess of Kent (Gaines'), Enchantress (Wilson's), Evadne (Garth's, Flash (Garth's), Grand Monarch, Gipsy (Foster's), Glory of Jersey, Jubilee (Garth's), Lady C. Shepherd, Madame (Lumsden's), Medora (Foster's), Prince of Waterloo, Princess Sophia Matilda, Van Amburgh (Wilson's), Witch (Garth's). Very strong and healthy plants at 30s per dozen.

Geranium alba, 3s. 6d.; Manettia bicolor (fine); Syphocampilus betulifolia, 2s 6d., Hedge[illegible]s. 6d.; with many other new Greenhouse Plants.

GENERAL DESCRIPTIVE CATALOGUES of Geraniums, Camellias, Fuchsias, Pansies, Verbenas, Cinerarias, Greenhouse and Herbaceous Plants, may be had, on application, by sending two postage-stamps. Their Catalogue of New FLOWER SEEDS, &c., is also ready.

A remittance or references from unknown correspondents will oblige.—West Nurseries, Durham, Feb. 12, 1844.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE & MORRIS will submit to Public Competition at the Auction Mart, Bartholomew-lane, on THURSDAY, Feb 29, 1844, and following day, at 12 o'Clock, about 400 DOUBLE CAMELLIAS, consisting of all the leading varieties, beautifully furnished with bloom-buds; also a fine assortment of STANDARD and DWARF ROSES, AMERICAN PLANTS, DAHLIAS in dry roots, &c May be viewed the morning of Sale. Catalogues may be had at the Mart, and of the Auctioneers, American Nursery, Leytonstone.

*** The Camellias will be sold on Thursday, 29th.

TO GENTLEMEN AND OTHERS ENGAGED IN PLANTING

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietors to submit to public competition, in consequence of the expiration of Lease, on Monday, March 4th, 1844, and following days, at 11 o'clock, the Stock of ONE OF THE KENSINGTON NURSERIES, next the Great Western Road, consisting of large, healthy, and well-grown specimens of Ornamental Trees and Shrubs of every description. Variegated and Green Hollies, Evergreen Oaks, and Cork Trees. Large Fan and other Yews, twice transplanted; Common and Portugal Laurels, Arbutus, Alaternus, &c.; Hemlock Spruce, Pinus Laricio, Austriaca, and Nigricans, &c. &c. These grounds have long been celebrated for the health and beauty of their Trees and Shrubs, and safety of removal, and well worth the attention of those gentlemen who intend planting in the spring. May be viewed prior to Sale. Catalogues one shilling each, returnable to purchasers, may be had on the premises; of the principal Seedsmen; and of the Auctioneers, American Nursery, Leytonstone.

FOR SALE.—Three pairs of SILVER PHEASANTS, last year's Birds (cheap). Apply to W. LAVE, Post Office, Andover.

TO GARDENERS, NURSERYMEN, and Others.

TO BE SOLD.—Four Acres of excellent Land in the best condition, with Stock, Greenhouses, Frames, Implements, &c. A commodious Dwelling House, with a good connexion of long standing. Can have four Acres more adjoining, if required, with immediate possession. For every particular apply by letter, to JAMES BLACK, 18, Charles-street, Kensington-square.

GRAINS TO LET.—Three Nells of Grains per week to Let, about 12 quarters each Nell. Hay, Straw, Corn, &c., would be taken in exchange.—Apply to Messrs. STAUNTON, No. 9, Strand.

AMERICAN FOREST SEEDS.—Messrs. Edmund Peirasse & Co., 3, London-street, Fenchurch-street, beg to inform Gardeners and Nurserymen that they have just received a large assortment of all the usual varieties of the above, which they are selling at low prices. The Seeds have been selected with great care by a gentleman long accustomed to supply the trade.

Circulars with a list of the varieties can be had on application as above.

THE LATE Mr. LOUDON.—A Public Meeting of the Friends of the late Mr. Loudon will be held in the large room of the Horticultural Society's Establishment, Regent-street, London, THIS DAY, Feb. 17, at Two o'clock precisely, to consider the best means of extricating his Widow and Daughter from the difficulties into which they are placed by Mr. Loudon's sudden death.

It is hoped that noblemen and gentlemen who patronise Horticulture, and also all Gardeners and Nurserymen who are within a reasonable distance, will attend.

NEW FUCHSIAS, VERBENAS, PETUNIAS, ANAGALLIS, &c.

WM. MILLER'S LIST appears in this day's Paper, offering his extensive Collections of the above Plants at very low prices:—as 12 distinct Sorts of choice Fuchsias, for 7s. 6d.; 12 fine distinct Varieties of Verbenas, 2s. 6d.; Anagallis, mixed Sorts, 4s. per dozen, &c. &c. &c. All sent post-free.

Providence Nursery, Ramsgate.

The Gardeners' Chronicle.

SATURDAY, FEBRUARY 7, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Tuesday, Feb. 20	Horticultural	. .	2 P.M.
	Linnean	. .	8 P.M.
Wednesday, Feb. 21	Society of Arts	. .	8 P.M.
Friday, March 1	Botanical	. . .	8 P.M.

Mr. Williams is, doubtless, entitled to the credit of having taken great pains to explain in a popular manner, and with reference to the actual ordinary proceedings of everyday business, the nature and proportions of the different materials which find their way into a furnace, and particularly for impressing on the consumers of coal the distinction which exists between the earlier and later periods of the act of combustion, or rather of the act of destruction; for the first step is obviously, as indeed it has been always called, a process of distillation, in which heat, so far from being liberated, is rapidly absorbed from that portion of the fuel which is in a more advanced stage of decomposition. This distinction creates the first difficulty which Mr. Williams proposes to meet; but there is a second, and perhaps greater difficulty, arising from the liability of the coal to form carbonic oxide instead of carbonic acid, a change which renders a given portion of carbon less effective as a producer of heat, in the proportion of 1 to 2.

Both these points have long been well understood by chemists, and in some measure by practical furnace-builders; numerous attempts have been made to diminish the unfavourable circumstances, and to substitute a better state of things; but hitherto without any decided success.

The importance of the first question—that which relates to consuming the volatile products, may be judged of, when it is remembered that each ton of coal produces from 8,000 to 9,000 cubic feet of common illuminating gas; the heating powers of which must be immense, if brought properly into action.

Great, however, as this is, it sinks into insignificance when compared with the possibility of forming carbonic oxide in large quantities. The published analyses of coal are too discordant to furnish materials for accurate inference on this subject; but there is no question that the carbon which does *not* accompany the volatile products—that portion which remains after the hydrogen has taken with it so much as serves to render it luminous—or, in other words, that portion which is represented by the coke in a common gas-retort, is the main constituent of the coal for producing heat. If, therefore, this principal ingredient be consumed in the formation of carbonic oxide, instead of carbonic acid—the former converting only half the oxygen which the latter requires—the loss, as before stated, is one-half of the total heating effects in so much of the carbon as is thus disposed of.

There is a third question which is sometimes raised, and which may be of considerable consequence, though there are no decisive experiments on the subject. It is stated that if the hydrogen be not consumed by the proper admixture of oxygen, it will have a tendency to combine with some of the nitrogen liberated from that portion of air acted on by the carbon, and the resulting compound would of course be ammonia, which is supposed (we know not how truly), to be positively injurious, independent of the negative evil of having lost the unburnt hydrogen.

This is not, perhaps, of much importance, because the hydrogen is worth turning to account, for the first reason; and if this be accomplished, the third point falls to the ground.

The action to which coal is subjected in a furnace, then, may be thus briefly described: The fresh fuel is, in the first instance, heated at the expense of the heat already existing in the furnace; it is then put into a state of distillation, occasioning a still greater expenditure of heat, inasmuch as this process demands all the so-called latent caloric for the purpose of volatilising the hydrogen; and although it is possible that this expenditure may be repaid, if care be taken to assure the combustion of these volatile matters before they are out of reach, there remains still the difficulty before alluded to, of a very different, and, indeed, almost opposite state of circumstances at different periods in the same furnace.

This is the point at which all the inventors start. Some (but these are a minority) propose an apparatus capable of being modified by hand, so as to be adapted to the different stages of fresh, half-burnt, and incandescent fuel. To do this effectually, however, requires more skill and more attention than can be reasonably expected. We must look, therefore, for a furnace which shall be the best for an average state of things, and submit to a little loss at the extreme periods.

To begin with carburetted hydrogen. It is certain that, in order to consume it advantageously, an adequate supply of unvitiated atmospheric air must be supplied to it. Some have contended that this may be done by freely supplying air at the ash-pit, so that more shall pass through the fire-bars than the carbon will take up, and they presume that the remainder will go to combine its oxygen with the hydrogen. Others have supposed that if the door above the fuel have an opening, air may there be admitted in proper quantities, and passing unaltered *over* the fire, will burn the rising hydrogen. A third class requires that the air destined to burn the hydrogen shall never pass within the sphere of the influence of the burning coals, but shall be admitted behind or beyond the fire. Finally, Mr. Williams says that it is not enough to admit the air at this place; the air must be split into small streams to secure its rapid and intimate mixture with the hydrogen, or else combustion will not take place.

Whether it be true that no air will pass through the burning coal (retaining its oxygen), however freely it be supplied, we cannot pretend to say; nor can we assert that it will be sufficient to introduce it in front, but *over* the fire, as secondly proposed. Neither are we disposed to deny that there may be a decided advantage in breaking up the admitted current into a number of small streams, presenting, it must be allowed, a greater quantity of surface to the act of combination than would be afforded by suffering the air to enter at one large aperture. We think, indeed, that, with reference to the place of admission chosen by Mr. Williams, this division is good; for although we cannot agree with his reasonings upon the subject, we think that this arrangement gives the inflammable gases a better chance of being burnt before they leave the furnace, or its immediate neighbourhood.

Mr. Williams's arguments for thus minutely dividing the currents of air we must consider on a future occasion.—*A.*

In speaking of the particular Diseases of Plants, we are not prepared to give a classification of them according to the principles on which systems of Nosology are ordinarily constructed. We shall, however, be obliged frequently to make use of terms which are employed to designate the diseases of animals; but we must warn our readers against supposing that there is any similarity between many of the diseases of plants and animals which have a common name. The important part which the blood-vessels and nerves play in the economy of animals must always produce a great distinction between their disturbed functions and those of the vegetable kingdom. At the same time, we must draw attention to the important fact, that *the tissues of both animals and plants originate in the cell*, and that probably no disease takes place either in the one or the other without one or more of the cells of which they are composed being more or less altered in structure.

The medical man divides diseases into *functional* and *organic*; and under the former head places all those diseases in which he cannot detect an alteration in the structure of the diseased organ; but this arises from his want of the power of observing the minute changes of structure on which the diseased function depends. There is no such thing as function independent of structure, and there is no evidence to prove that a function can be deranged whilst the structure is quite perfect. From the simple forms which the tissues of plants assume, we can much more easily detect slight alterations in their structure than can be done with those of animals. We shall therefore assume that there is no such thing as functional disease in vegetables, and that when disease occurs amongst them, it depends on altered structure, however little this alteration may be observed.

In the great majority of the diseases of plants, a change of structure may be easily seen, and in no case more evidently than in that form which we shall call *gangrene*. This is a term used in animal pathology to indicate the first stage of mortification or death of a part, and may be appropriately applied to the same occurrence amongst vegetables. Gangrene is most frequently met with in the leaves, fruits, and stems of plants, and of these parts, those which are most succulent are most liable to its attacks. It is divided by German writers into *moist* and *dry* gangrene; the moist occurring in the succulent parts of plants, and the dry attacking the woody parts, as the stem, of shrubs and trees. In this country all the forms of gangrene are frequently called *canker*; but this term is more especially confined to a peculiar disease of the bark and stem of Apple and Pear-trees, to which alone we think it ought to be applied, and on which we shall hereafter have occasion to make some remarks.

We shall speak first of Moist Gangrene, as we have recently had some inquiries made concerning its attacks. Of the families in which this disease occurs, it is probably most frequent in the Cactaceæ and Mesembryaceæ; it is, however, not uncommon in the Cucumber and Melon and other fruits, and attacks the Balsam and other succulent plants. On its occurrence in a plant, as in the species of Cactus, the stem is found in different parts to have spots of varying size, which at first have a darker green colour than the surrounding parts. The centre of these gradually changes colour, becoming first yellowish and then of a dark brown or black colour; whilst the circumference of the spot goes on increasing till it embraces the whole of the stem, the same changes of colour being observed. At first the affected parts appear slightly swelled; but they at length contract, and the epidermis bursts, and from the opening thus formed, a dark fluid oozes, which has a fetid, disagreeable odour. If allowed to go on, the disease spreads to the whole plant, the tissues become rapidly disorganised, and an almost entire decomposition of them ensues. On examining under the microscope the tissues of a plant thus affected, before its organisation was destroyed, we found that the greatest difference that existed between the sound and the diseased parts was in the colour of the cells. The diseased cells were much darker in colour, arising from containing in their interior a number of dark granules. They were most abundant near and in the bark, indicating that the disease commenced at this part. They were also more evident in the sounder parts around the hardened masses which are so common in the tissue of Cactaceæ. The fluid which oozed from the diseased parts was filled with irregular-shaped dark granules, of the same size as the regular transparent granules of the fluid of the healthy tissue. In some specimens of the Cactus speciosissimus attacked with gangrene, which we recently examined, we found in the diseased fluid a number of animalcules, apparently belonging to the genus Vibrio. Their body was cylindrical, tapering at both ends, and having the movements of a minute Gordius. We can draw no conclusions from this observation in a single case, but it is interesting in connection with the fact that an animalcule belonging to the genus Vibrio produces the disease known by the name of "cockle" in Wheat.

With regard to the causes of this disease, both cold and moisture will produce it. Succulent plants are susceptible of the action of cold, and if this is long continued the processes of life are no longer carried on, and the laws of chemical action begin to prevail, and the consequence is the departure of vitality and the appearance of this disease. Moisture, either in the soil or in the atmosphere, in too great quantities, will bring on gangrene, and more especially when combined with a low temperature. A too great quantity of water in the tissue, which may occur either from there being too great a supply to the root, or too little facility for getting rid of it by exhalation, will deprive the plant of vital power, and expose it to the destruction of its tissues, from the prevalence of the laws of chemical action.

Such being the cause of this disease, the treatment must always be directed to the immediate removal of them. The diseased parts should be cut away, and every precaution taken to insure a proper amount of temperature, a drier atmosphere, and drier soil. But it should be remembered that these are only relative terms, and that what may be an excess of cold or moisture for one plant, so as to produce gangrene, may be for another plant of the same genus only that which it requires for the performance of its healthy functions.—*L. E.*

BEES.—No. VII.

(Concluded from p. 83.)

The Destroying of Bees and the Uniting of Swarms.—The time of taking or harvesting honey depends upon the locality, the state of the weather, and the lateness of the season. The proper time is when the Bees begin to eat more than they gather; and this, generally speaking, takes place about the 1st of September. In ordinary fine seasons your second swarms and turn-outs will weigh from 30 to 50 lbs. From these you should select some for stocks, the first swarms being generally too heavy. Choose those that have bred well in July and August, that are full of combs which consist of worker-cells. If you should select a first swarm for a stock, be sure that its queen is not three years old. If it is old kill it, and put a young one in its place; for you will, by allowing a queen to die a natural death, incur the loss of about 1*l.*, that is, if your hives are large. If you should select a second swarm or turn-out, that has an unprolific or an untimely-impregnated queen, destroy her, and put a whole swarm with a good queen into the hive. The uniting of swarms is a very simple concern. After having drummed the Bees out of one hive into an empty one, invert the hive into which they are to be put, and throw them *en*

access into it, sprinkling a little sugar and water over them previous to placing it on the board. This is an infallible way of uniting swarms. The proper time to do it is about sunset. But be sure never to do anything with Bees when you are perspiring, the odour of perspiration being peculiarly offensive to them.

Almost everybody knows how to kill Bees. A pit is dug, one edge of which is undermined, in order that the ignited rag, previously dipped in melted brimstone, may not be extinguished when the Bees begin to fall; the hive is placed over the pit, and the soil is thrown round it to keep in the smoke. Some people seem to think that it is cruel to kill Bees in this manner, but I contend that it is as cruel to kill a bullock to get beef, or knock a calf on the head to get milk, as it is to kill Bees to obtain honey.

The taking of Honey and Wax.—Various systems are adopted to take honey from the combs. Some cut the comb piecemeal, and put it into a bag, which is hung up before the fire; some take the lids off the cells, and cause the honey to run through a cloth; and some squeeze the honey out of the comb with the hand. The last is the most speedy way—one man being able to take from hives, squeeze, and run through a bag, 150 lbs. in one day. That the combs may not contain brood when you take the honey, it is advisable, in many cases, to kill the queens three weeks before you massacre the Bees. Swarms will probably issue on or about the 18th day from that on which the queens were killed, but let them go—they are valueless—the season is over. Wax is made like dripping. The combs are boiled in water till all the wax is on the top, when it is ladled into a bag, which is placed on a board in a large tub, and then pressed hard with a small wooden roller. It is boiled again in clean water and put in milk-pans, where it congeals and forms cakes. The boiling wax may also be run through a hair sieve.

The Enemies and Diseases of Bees.—Bees themselves are their greatest enemies; they are very apt, particularly in the month of September, to rob one another. In the month of September, a mouth-piece, that is, a bit of wood with a hole therein large enough to allow the Bees to drag out their dead, and small enough to keep out mice, which are also enemies, should be fixed in the door of every hive. The entrance to the castle is therewith more easily guarded. Still, if one hive be invaded by the Bees of another hive belonging to yourself, the invaders ought to be removed to a distance for a week or two; but if the invaders do not belong to yourself the invaded hive ought to be removed. There are only two diseases of Bees that merit notice in a concise article like this. One of these is caused by back-gone broods, the other by watery honey. The limits which circumscribe my remarks forbid my enlarging on them. Bees never thrive well where there is a back-gone brood; indeed, its unpleasant odour sometimes causes the Bees to leave the hive. In rainy or dull summers Bees are apt to collect honey before the flowers are quite dry. In winter this honey becomes sour and poisons them. I knew a man who gave 20*l.* for 20 stock-hives in autumn. Before the spring following they all died but three, one of which was in an unhealthy condition. Notwithstanding this great misfortune, he realised 20*l.* from the produce of the three during the first year, and it is thought increased his stock of hives a little. Sugar and water are the best remedy. In autumn, straw covers should be put on hives, to protect them against the inclemency of the weather. When snow is on the ground the doors of hives ought to be kept shut; the Bees being apt to come out when the snow is melting, into which they fall and die.—*A. Pettigrew, Wrotham Park, Middlesex.*

THE SPRING MANAGEMENT OF HALF-HARDY PLANTS INTENDED FOR MASSES OR GENERAL DECORATION.

It so happens with the majority of gardeners as well as amateurs, that, through a deficiency of glass, one frame or pit must play in its season many parts. Now, it is very necessary to know how to economise in these matters. It is comparatively easy to produce everything in its season in first-rate establishments, where, instead of there being a want of glass, there is a pit or pits always at liberty. But to make a little glass go a long way, and in some degree to endeavour to compete with more complete establishments, requires considerable knowledge of first principles, and a clever application of them. At this season, those who are placed in the last predicament, are sometimes puzzled to know how to discharge the winter tenantry of frames, wanted for early Cucumbers, Melons, Potatoes, Carrots, &c., with as little injury as possible to these delicate tribes. I will, therefore, detail my mode of accomplishing this, which I have found very successful:—In the first place, a most material point is to take care that the various cuttings, &c. intended for flower-garden decoration are struck early and well established in their store-pots before the winter sets in, as in the event of their being propagated late, they will require to be watered late in the season; and here lays one of the prime secrets in the affair.

Flower-garden stuff of the above description I take care to get into their store-pots by the beginning of September: my mode of potting stores is this:—After a few very rough crocks in the bottom, I place a layer of clean riddled rough old tan to within four inches of the top of the pot; the stores are placed immediately on the tan, and the pots are filled up with a compost, of which one-half is strong or stiff loam in a rough state. Now, this stiff loam is well known to be very retentive of moisture; and when the stores lay hold of this soil firmly, there will be no occasion for watering; they will stand any amount of drought all the winter in very low temperature. The plants may root, shape, flag a little at times, but this is in favour of the whole process. Under these circumstances I always withstand the temptation of watering. Here, then, is a principle of acclimatising, and abundance of air at all times, excepting during hard frosts, is all that is wanted; only keep to these principles, and frost will have less effect. In the first or second week of February, I begin to prepare for removing them; and the first thing to be done is to inure the plants for a week or so, previously to a lower temperature, viz., to a little frost; this is done by refraining from night coverings on evenings which promise a small amount of frost; for, by this time, if they have not been petted, they will endure a little frost, observing that when the weather is very hard, viz., sunny days with intense frost at night, not to uncover in the day; do not let them see the sun by any means; let them remain at rest. The same principle applies to Lettuce, Cauliflower, &c., of course in frames.

This preparation completed, I throw out a trench on the north side of a wall, before my Morello Cherries: the trench is from 2 to 3 feet deep, and 3 feet wide at bottom, sloping to 3 feet 9 inches at top; the plants are lowered into the bottom of the trench about the second week of February, or perhaps the third, according as the frames are wanted—observing to take out some of the very tender kinds, or those liable to canker, as also any kinds from which it may be necessary to propagate; the latter being placed in heat to excite young wood for cuttings, and the former set on shelves in a cool greenhouse or Peach-house.

These cool pits have straw mats for covers, which are made by me from old hacked-out lights, by merely placing new and good straw transversely across the bars, and then tyeing down three laths or strips of wood longitudinally, from one extremity of the sash to the other; these hold the straw firmly in its place. This kind of straw hurdle is very economical and efficient, as two men can make a dozen in a day, and they do to cover Lettuce, Salads, &c., at various periods of the year.

The only management the plants require in their new habitation is to keep the straw hurdles closed down for a couple of days at first, or partially tilted, and to let them occasionally remain on through very cutting winds, observing to close them down always at night, unless in very mild weather.

Towards the end of February they may receive their first watering, taking care to give it but sparingly, and very seldom, until they begin to grow, when they may be potted off singly for masses. It is astonishing to witness the progress they make after coming from these cold pits, and getting into warmer habitations, as they never obtain a glimpse of sunshine in the cold pits.

Much mischief arises to various plants in frames from sudden vicissitudes of weather, especially that of warm sunny days during intense frost. I make it a rule with plants that will stand a little frost, such as Cauliflowers, Lettuces, &c., to get them frozen tolerably hard whenever frost occurs, after they have become hardened (say through December and January), and then to cover them up close with straw, which I never remove while I can keep them frozen; indeed it must not be removed suddenly when a thaw takes place Darkness has no prejudicial effect on them while they can be kept frozen. I have had them in this state for three weeks at a time, with no injury therefrom.—*Robert Errington.* [Excellent advice.]

A KNOWLEDGE OF PRINCIPLES ESSENTIAL TO THE BEST CULTIVATION.—No. II.

(*Continued from page 84.*)

In the process of shifting, whether it be a single and accumulative one or repeated shiftings, it should be remembered that the amount of soil to which any plant is subjected should in all cases bear a strict proportion to the intervening period between the process of shifting and the season of bloom. For instance, Fuchsia tricolor is well known, beyond most varieties, by its premature disposition to form flower-buds, consequently (unless it manifests an exuberant primary growth) it should be excited earlier than others, in order to secure a longer period of growth previous to its season of flowering. A second instance occurs in Fuchsia conspicua arborea (of a noble and distinct habit), much larger in its growth, and later in the formation of its bloom, but not less certain and profuse when its maturity is attained. Thus, two extremely opposite-habited plants are equally fertile under their essential conditions of growth, and hence the error of applying one rule to both.

Other instances might be adduced to show that the most luxuriant growth, of which some plants are capable, is the only direct and certain mode of attaining fertility—as, for instance:—Costus Nepaulensis, and Acacia Kermesina, (the former with white blossoms, enveloped with crimson sheathes; the latter with an elongating spike of elegant crimson tassel-like flowers) both beautiful stove plants, totally dissimilar in structure as well as in the soils essential for their growth, but each requiring a luxuriant annual development of growth to ensure a perfect bloom.

Many objections will, doubtless, be made to an exuberant growth, as being unfavourable to fertility. Other conditions being favourable, I would still urge that the highest capability of plants is generally involved in their most extensive and luxuriant form of growth. An objector would add, "restrict the proportions and cramp the energies of a plant, and I am sure to obtain a certain extent of bloom." I would rather say, where the highest effects are sought for, "provide the means for its perfect growth prior to the season of bloom; encourage Nature to mature its legitimate proportions, and you will ensure a uniform and perfect result."

Apart from the highest known vigour of any given plant, it appears impossible to ascertain what are its capabilities of fertility. I would say to a cultivator, shew me what you deem the most perfect extent of growth in any given plant, and I will define the average excellencies of the same under every other condition of growth. Can there exist any doubt that if the knowledge of any tribe of plants, say Heaths, Pelargoniums, or Pine-apples, should lead to a larger and more perfect growth, that such an advancement will not lead to the attainment of a greater extent of perfect bloom and larger fruit?—Verily not. As every plant is capable of a certain extent of growth under the most favourable circumstances, it may be assumed, that a system of cultivation, equal to a perfect growth, is essential, and antecedent to a perfect development of bloom.

That there should often exist a striking difference in the application of principles to the operations of art, is far from surprising, when the differences connected with professional experience are duly considered, as well as the counteracting influences which a defective education often exerts over men's capacity or taste. How often have early impressions formed habits of preference, until tyrannical custom has become confirmed prejudice. How often have facts proved impotent, until reason has asserted its right to question the opinions of others, and to ascertain the truths upon which such opinions are founded.

These remarks have, in part, been suggested by those of a Correspondent at p. 892 (1843) where an objection is made to the principle that is involved in that mode of cultivation which says, that "plants the most difficult to rear should be removed at once from the cutting or seed-pot to the one in which they are to be exhibited as specimens." To all such criticisms I answer that I have no objection to the method which the correspondent alluded to prefers in his own case, namely, to "have a plant thoroughly established in a small pot before it be removed to a larger one," provided that such a rule is not substituted for the principle upon which my statement is founded, and upon the correct application of which the highest effects of cultivation depend. I will even add that a gardener may be justified in giving a second shift prior to the final one, if such a process is more compatible with his skill, or with the means at his disposal for maintaining a course of treatment sufficient to produce the requisite effect. But any rule which seeks by a repetition of causes for an effect which Nature would produce by the immediate application of one, I do not consider entitled to the name of a principle—which is a fundamental law of Nature. If, for instance, one gardener considers the establishment of a plant in a small 60 of essential importance previous to its removal to a 16 or 12, another may insist upon a further shift to a large 60 or 48 before removal to a 12 or 8, and thus each would claim for his rule an importance which can only be conceded to a principle.

Principles are to be learned, not improved. Their apparent impracticability and variance with general practice in no respect lessens their value, which is determined by their truth, and not (necessarily) by their application. —*William Wood, Pine-Apple Place.*

FAMILIAR BOTANY.

Morphology.—No. III.

"Le Sphinx n'est plus assis sur le seuil de notre temple!
Pour jamais les secrets s'ouvrent à tous les yeux."

Although sound physiology refuses to sanction, in their full extent, the views entertained by Linnæus, and notwithstanding that it teaches us to know that the process of anticipation is imaginary, yet it is impossible not to admire the farsightedness of that great man, which enabled him to perceive the general nature of the great truths with which the Morphologist is now familiar. His contemporaries, however, in general were so wholly destitute of a philosophical spirit, that they were unable to appreciate the value of his speculations. For them a flower was a flower, a fruit a fruit, and a leaf a leaf. They were contented with the barren knowledge that such organs existed, and it did not enter the imagination of the dull school which Linnæus founded to inquire on what plan they were constructed or by what means the wondrous variety, so eminently conspicuous in the vegetable kingdom, was provided. Occupied with counting the stamens and pistils of a flower, they never considered the general laws of organisation worthy of their study. There was, however, one great exception.

Dr. Caspar Frederick Wolff, a Prussian physician, and one of the Professors in the University of St. Petersburgh, described, in the year 1768,* the manner in which the parts of plants are formed out of leaves, with so much accuracy that modern investigations have done little more than confirm his views. "A man," said Wolff, "must be very dull who cannot perceive that in some plants the calyx is but slightly different from the leaves, and is in fact nothing more than a collection of many small and imperfect leaves. Many of those annual plants which have composite flowers show this very clearly, for you have in those instances leaves becoming smaller and more imperfect as they rise up the stem, until at last those which are highest of all become extremely small, are closely clustered together, constitute the segments of the calyx, and in their mass form, in fact, the calyx itself. The seed-vessel in like manner is plainly formed of leaves, with this difference only, that the leaves which are merely collected together to form a calyx, are in the seed-vessel glued together. This is proved not only by the capsules of many plants which, when they are ripe, split into the

* Novi Commentarii Academiæ Scientiarum Imperialis Petropolitanæ, vol. xii., p. 403.

leaves, or parts, out of which they are compounded, but by the actual structure and external appearance of those parts. So, again, seeds, although at first sight they seem to be so different from leaves, are really true leaves glued together; for the seed-lobes into which they split are but representations of leaves, although indeed imperfect, shapeless, small, thick, hard, dry, and colourless. If you doubt it, only observe how those lobes, when the seed is committed to the earth, by degrees expand into a perfect green succulent foliage. As for the corolla and stamens, that they are only modified leaves is made manifest by many observations. We often see the divisions of the calyx change into petals, and these, in like manner, alter into a calyx; and here, as the calyx is manifestly composed of leaves, and the petals are of the nature of a calyx, it is clear that the petals are also modified leaves. In like manner, we see in polyandrous plants stamens degenerate into petals, and so form double flowers, and then again petals return to stamens: a sufficient proof that stamens also are of the nature of leaves. In short, in plants, wonderfully and admirably as their parts are constructed, all things considered, I can recognise nothing except leaves and stem (for the root belongs to the stem)." And further on, he declares, that his observations have convinced him that "As the force of vegetation diminishes various changes are brought about, and that all the modifications of leaves consist merely in a deficiency of perfection (*in defectu perfectionis*)."

In the year 1790, the poet Goëthe, knowing nothing of the writings of Wolff, but acquainted with the speculations of Linnæus, published his Inquiry into the Metamorphosis of Plants* in the form of a pamphlet of 86 pages, in which he demonstrated, in considerable detail, the truth of most of Wolff's views, and finally laid the solid foundations of what is now called Vegetable Morphology. But at the time when his doctrines were promulgated, Goëthe, like Linnæus and Wolff, found the world too much occupied with the surface of things to trouble itself with inquiries the end and aim of which it was unable to comprehend; and it was in fact full 30 years after the appearance of the last-mentioned work that the science of Morphology became fully established. Since that time it has made such progress that it is, I think, impossible now to name a Botanist of any eminence who entertains a doubt upon the subject; which is justly regarded as one of the clearest manifestations of the power of Him "which doeth great things past finding out; yea, and wondrous without number."—*R. E.*

* Versuch die Metamorphose der Pflanzen zu erklären, Gotha, 1790.

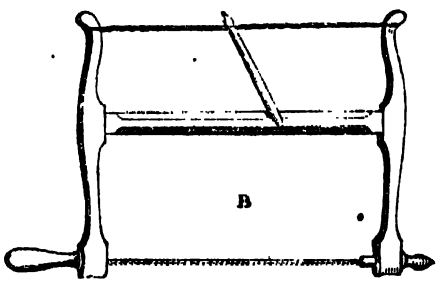
THE ROSE-GARDEN.—No. V.

(*Continued from page 84.*)

Sorts of Stocks for Different Roses.—Different Roses require different stocks. A tree that of itself would make a yard of wood in a season, is confined and injured in its operations, by having, perhaps, a single bud upon it of some rare and tender sort of Rose, which makes but feeble and delicate shoots. If left to itself under such circumstances, the extra sap would find a speedy mode of escape, by sending forth innumerable shoots from below the bud, and the bud would soon have but a bare subsistence. Roses which are free growers, such as the Noisette, &c. will generally be found to succeed better upon the wild stock than others, their habits of growth being more assimilated. The Wild Briars grow very late in the year, perhaps more so than almost any other wild plant; and the free-growing bud avails itself of, instead of checking, this propensity, and draws up the whole sap the standard can produce; thus keeping up the full activity of the tree, thriving and recovering a stagnant stem better, and being less encumbered with suckers than delicate sorts. Comparatively speaking, the White Moss, on the contrary, can hardly be kept alive when grafted upon the Briar.

Again, if a free-growing bud, such as the Noisette, Greville, &c. were put upon a small stock, the bud would entirely drink up the sap of the stock; and, instead of making a fine bushy head, would either grow in one long shoot, or, at all events, make a small and mean head, in comparison to what it would have done upon a larger stem. Stocks, therefore, should be chosen with reference to the purposes they are intended to be put to; the bringer being desired to cut them above the first fork (both in order that the whole stem may be preserved, and that the strength of shoot they are likely individually to produce the succeeding summer, may in some degree be judged of from the quantity of head to be cut off, and its clean and healthy appearance); it should be remembered that stocks being so very easy to procure, none but the very straightest and best should be chosen; and the rejected ones may be planted in some out-of-the-way place, to be used in case they should be wanted. About a third more stocks should be chosen than are absolutely wanted, and the others may be laid in the ground, as a *corps de reserve*; they will most likely be worked in the season, and without costing any trouble, except as to budding, according to their health and strength; the advantage of a supply of different heights, sizes, and sorts will be obtained.

When the stocks are taken up, they should be kept as short a time as possible out of the ground, as the air injures the root. This is of the greatest importance, as the strength of the expected shoots will mainly depend upon it; but if they have been weakened by lying out of the ground, they will regain a portion of their strength by being much shortened in the stem; for the roots of all trees being proportioned to the trunk they have to maintain, it is evident that an injury to the one should be followed by a reduction of the other; and thus, to a certain extent, the more head removed in the autumn, the freer supply of new wood will be produced in the spring.



If it be desired to keep stocks some time before planting, they must, like all other trees, have their roots covered with mould, which is technically called, laying in the heels. When stocks are sent any distance, a puddle of clay and water should be made, and the stocks dipped in it, so as to form a coating to defend them from the wind; and then, being packed up in an old bass-mat, they will carry without injury.

The trimming of the stocks is next to be considered; first, as to the requisite height; secondly, as to the mode. The heights most desirable are, four feet, three feet, two feet six inches, two feet, one foot six inches, one foot.

The manner is, by a clean slanting cut, at about an angle of fifty degrees, the upper part of the remaining stock being a quarter of an inch above a bud. If the bud be not enough marked to show its position, let the lower part of the slant be that distance above the ring denoting where the bud is to spring from, and the extra plant can be afterwards removed. The object of cutting so near to a bud is, that when the first shoot starts, the bark may begin to form over the wound; but if there is any distance between the wound and the base of the new shoot, this will not be the case, and the dead wood will gradually eat into the stock. If, therefore, the excision is not made in such way that the stock may begin to be covered the first year, it will be better to leave a few inches (viz., as much as is between the bud cut off, and that desired to produce the new shoot,) that the tender shoots which spring from the inserted buds may be tied to it, delaying its removal till the graft has become strong enough to heal the wound when inflicted. This will in general be about eighteen months after budding, when care must be taken to cut close to the base of the shoot, which enables the rising sap to cover the wound more easily. In all cases the wound should be covered with either the undermentioned mixture immediately, and a small piece of grafting clay, or, at least, a little mould should be rubbed upon it.

Trimming the root is a matter, if possible, of even more consequence, because but one more opportunity will be afforded of reviewing this part of the work, and perhaps none of retrieving mistakes. The longevity of the plant depending mainly upon the roots, it is necessary to shorten all those which are long and thick, and to remove heavy lumps and clumps of unserviceable wood, leaving, as nearly as possible, only such parts as are furnished with small fibres and roots. This will afford an opportunity of planting the stocks with greater care; and of forcing them to make fresh shoots, (which, in good ground, they will be sure to do,) and thus continue to improve. The roots, however, requiring the *same attention* as the branches, for a closer investigation of the subject, see *Transplanting*. It is, therefore, only necessary to add here, that attention must be paid to these points; and for the greater convenience of cutting the roots which are sometimes twisted and in cramped positions, it will be desirable to borrow a carpenter's small saw, of this shape, as well as a hand-saw, and thus

every facility being afforded in cutting the roots exactly as they may require, the work will be much expedited, as well as improved; but it must be remembered, that wherever a saw is used, either to root or branch, the surface left must be smoothed over with a knife.

Having finished these operations, and ascertained the heights desirable for the stocks, this is the proper time for shortening them, previous to planting in rows for budding upon.

Mixture to heal Wounds, and Mode of Application.—Five-eighths of black pitch, one-eighth of resin, one-eighth of tallow, one-eighth bees'-wax:—or, half bees'-wax, half pitch:—or, one pound of white Burgundy pitch, a quarter of a pound of black pitch, a quarter

(*To be continued.*)

Home Correspondence.

Farming and Gardening.—About here, there is a strong prevailing prejudice expressed in the term "that good gardeners make bad farmers." Why this idea should exist I cannot discover, unless the pursuit of Horticulture is supposed to absorb the attention so much as to cause the farm to be neglected, (which can only refer to enthusiasts or mere florists,) as the numberless phenomena to be observed in garden cultivation, and which may escape the notice of the farmer, might be generalised by an intelligent mind, and frequently applied with advantage to the larger business of the field. It is true that there is scarcely a farm-house without its garden, but when it is a large and ornamental one, in nine cases out of ten it owes its beauty and utility to the care of the lady and not to the master, who, if a money-getting man, grudges the land and perhaps the labour, and sometimes even the manure necessary to provide the kitchen with Cabbages, Peas, or Potatoes, and particularly whenas the mistress also thinks more of feeding calves, churning, or brewing, than of ornamenting her table with a bouquet. We may be sure if an early dish of Peas is forthcoming, a fine head of Celery, or a large bunch of Grapes, that the lady has extended her cares to the garden. I know of only two instances in this neighbourhood where farmers make the garden an object of attention; they have each a collection of plants, an abundance of good vegetables, and excellent fruit all the year round; nor are they behind any of their neighbours in the management of their farms, the land is drained, the fences well kept, and they take prizes at the Agricultural shows. In all the other instances of a tolerable garden to a farm-house within the range of my observation, the lady of the house directs the "rotation of crops," preserves the seeds and bulbs, and takes jealous care of the fruit; purchases the plants, and distributes the flowers. Whether this cheerful and necessary appendage to a farm be "kept up" by the farmer or his wife, may not signify much to the supply of Horticultural products for the house; but it does signify greatly that the man should be interested, if he only wishes to avail himself of the information conveyed by the *Agricultural Gazette*. All cultivation on a small scale is *gardening*, such as experimenting on manures, reproducing small parcels of picked seed, examining the relations of certain soils and vegetables, and acquiring a knowledge of the pernicious or useful properties of the different families of plants (as of the Flax Dodder last week). A farmer, adapting himself to the necessities of the times, must become more and more familiarised with gardening operations, and this extending to a habit will also induce a spirit of inquiry, and he will reconcile himself to become in theory, as he already is in practice, a botanist, a chemist, a geologist, and a gardener. —*J. W., Peterborough.*

Gas Tar.—I have tried this substance repeatedly for some years upon fruit-trees in my nursery, and in all cases it has answered the purpose of keeping off hares and rabbits, and instead of being injurious, I imagine the trees are benefited by its application: the only thing necessary to be observed is, that it must be applied when the trees are in a dormant state—say from November to March; if done at any other season it is certain death. My attention was first directed to the use of gas tar by Mr. Elliot, woodman to the Earl of Carlisle, at Castle Howard, where forest planting is done annually to a great extent, and where game is so numerous that it is necessary to apply gas tar to every tree that is planted. At this place it has always answered the purpose of keeping the hares off, and does no injury to the trees.—*William May, Hope Nursery, Leeming-lane, Bedale, Yorkshire.*

Greenhouses and Engine-houses.—A correspondent suggests that engine-houses are well calculated for greenhouse plants, as they are well lighted and heated by the sun and engine, and the work-people have no access to the room. He informs us that Messrs. Wrigley, of Cobster Hill, Oldham, have, in an engine-house connected with their cotton-mills, several Orange-trees in good health, producing moderately-sized fruit.

Cucumbers.—We last week gave a report of the Cucumber exhibition at Ipswich. Since that time we have seen the prize fruit of Mr. Leathes and Capt. Aplin; and we feel bound to state that they appear to us to realise all that can be accomplished by Cucumber-growers. We seldom see such fruit about London *at this time of the year.*

A Natural Mode of Destroying Insects.—During the present severe weather my gardener caught half a dozen of the Blue Titmice (Parus cæruleus), only one of which I succeeded in placing in my greenhouse, with the intention of hereafter setting it at liberty. No sooner had I turned it amongst the plants than it commenced assiduously to clear them of insects; and to my surprise and gratification, I have observed that many which I could not properly cleanse myself, particularly Cinerarias, have been completely freed from these unwelcome visitants; nor has, so far as I could observe—and I carefully examined one or two of the plants—the slightest injury been sustained; and I have enjoyed the greatest amusement in being a spectator of my little captive's labours.—Oleas.

Pruning Forest Trees.—If I were assured by Mr. Hamerton that he had ever seen five acres of plantations or one hundred trees on hedgerows pruned for five years in succession, his objections to pruning might have some weight; but in the absence of this proof I must be allowed to maintain my opinion of the advantages of judicious annual pruning, founded on the experience of 30 years. The plantations at Nerquis have been inspected by numerous individuals of the highest respectability, who bear testimony to their flourishing condition. Mr. H. should also not forget that the land thus planted cost only 1*l.* per acre at a time when property of this [illegible] was more sought after, and that its high situation, [illegible] feet above the sea,) soil, and cold climate, are adverse to the growth of trees. By reference to the *Gardeners' Chronicle* of Sept. 16th and 30th, Mr. H. will find [illegible]h at the bottom, and at seven feet in height, and also the height of clean straight timber, without a branch. The popular feeling against pruning has its origin in the wretched manner in which ignorant planters at uncertain intervals mangle their trees with hatchets.—*Philo-Sylva, Northampton.*

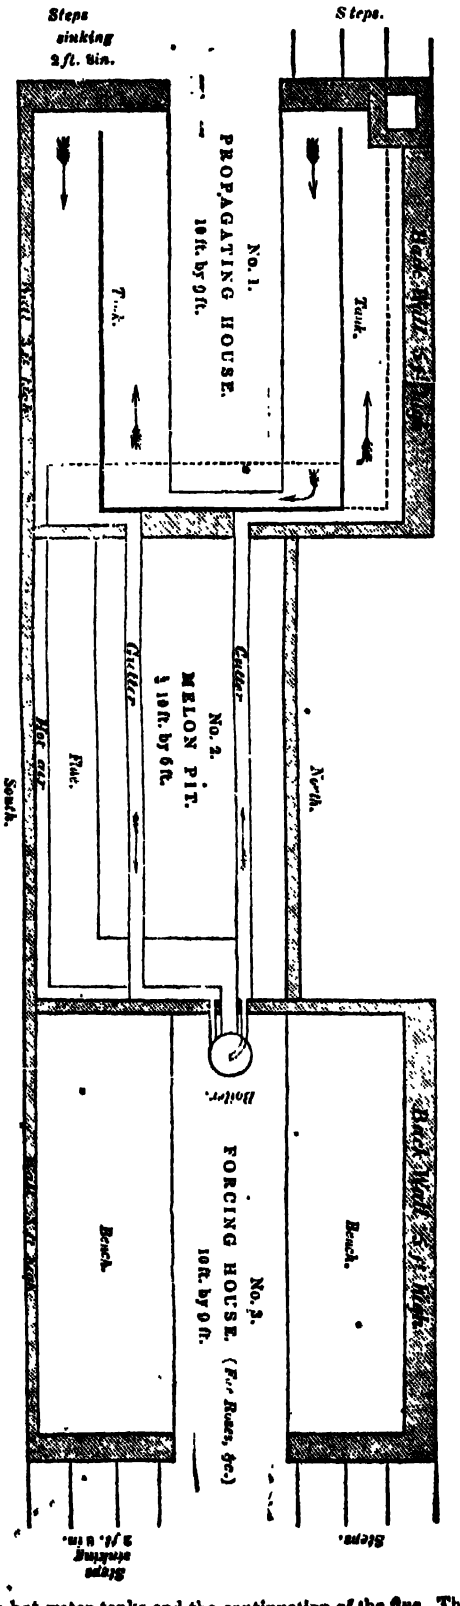
Pruning Forest Trees.—This subject is one which it is impossible to urge too much upon planters, as involving consequences of the utmost importance to the successful issue of much of the extensive planting which now exists over the whole country. I can speak with great confidence of the certain approval which the mode of pruning

as pointed out by Dr. Thackeray must gain for itself, if only fairly and properly tried. The result of it, as Dr. Thackeray states, is "that the sap, which the cut branches would have exhausted, gives vigour and increased strength to the trunk." And why is this the case? Because the sap which nourishes the tree is not only equalised where the trunk most requires it for the production of timber, but the sap so produced is of the most healthy and nourishing description; since the never-failing result of the principle of pruning rightly practised, is to send out leaves from the lateral branches, and these, too, of a fine, full, healthy kind, and in which of course the sap is elaborated.—*R. P. N., Hallyburton.*

How Bees collect Pollen.—Many are unacquainted with the use of the balls of pollen seen on the legs of Bees, as well as ignorant of the way in which they are collected. Reaumur and Buffon, for instance, considered them the elements from which Bees formed wax; this remains uncontradicted in a work by the latter even as late as the year 1821. Another author states that "she (the bee) gathers pollen from flowers with her mouth into round, balls; she sticks these pellets into two hollows, which are on the outside of the same joint on her hinder legs." Bees store up pollen solely as a provision for their brood. Wax is secreted through the segments under their bodies, but it is doubtful how they come by it previous to that singular process. As Bees frequent plants abounding with wax, I imagine that they collect it from them in the same way as the Wasp does its materials from decayed wood, or the Aphis, which produces the glutinous substance sometimes called honey-dew, that differs but little from the saccharine juice the insect had previously sucked from the tree or plant it infested. Some considered Bees' wax to be a "concreted animal soil." Amongst those who held this opinion may be ranked an excellent apiarian, Bonear, who was perhaps as nearly right as some scientific men, when he observed that Bees might produce wax in a similar way as that produced in his own ears. It is worthy of remark that Bees have produced wax when fed on honey and sugar—hence arises the belief that Bees form wax from these substances. But in such cases it is difficult to say what store of wax Bees might have in themselves before confinement. The balls on Bees' legs are accumulated by the insect putting one of its fore feet, which serves as a kind of brush, into a flower and then placing it between a series of strong curved hairs on its hinder legs, where the pollen adheres and forms the little balls. A superficial observer might suppose that Bees collected pollen by "rolling themselves in flowers," in a Hollyhock, for instance, for in such flowers, abounding as they do with pollen, they cannot avoid being dusted with it. "Mealy Bees" may be seen entering and issuing from the hive; the pollen that happens to fall from them when depositing their loads discolours the combs. The colour of pollen depends on the colour of it in the flowers the Bees frequent. Some writers say that Bees collect the greater part of their pollen in the morning, but as dry weather is most favourable for that purpose I imagine that a little farther in the day is more suitable for gathering it, as well as honey; both are alike essential to the prosperity of the colony. Much pollen or Bee-bread being often found in tenantless hives is no proof to the contrary. Bees live on honey, their larvæ upon Bee-bread, as already noticed, and they come more slowly into existence, as the former falls short, owing to want of attendance and lower temperature, occasioned by the Bees dying off. These remarks account for Bee-hives being deserted whilst they contained abundance of pollen in good preservation. —*J. Wighton.*

Feeding Bees.—A Correspondent recommends feeding Bees with loaf-sugar, as moist sugar produces diarrhœa. He is quite correct as to the danger of diarrhœa being produced by moist sugar, particularly by the coarser sorts, and as a preventive I would recommend a small lump of common salt being placed upon the board close to the entrance of each hive. This the Bees are fond of, and it has proved with me a certain cure for diarrhœa. About three years since my Bees were attacked in a most alarming way by that disease, and before I was aware of it I had lost nearly two-thirds of every hive. I then ordered my gardener to place the salt as before mentioned, and, after one or two days, I did not lose another Bee. —*A. F.*

Potatoes.—The subject of Potatoes failing in coming up after planting, is attributed by some to their being planted in one soil for a number of years. They say that the Potatoes gradually deteriorate, and lose their vegetative principle; but this does not always occur. I have planted one sort, known by the name of the Bread fruit, for the long period of twelve or fourteen years, and they are not in the slightest degree altered, either in size, crop, or flavour; they are of a dry and mealy nature. There has not come under my notice one root that was diseased. I fully agree with Mr. Wighton, that the late sorts of Potatoes should not be planted until the latter end of May, or the first week in June.—*Herbert, Sussex.*



Campanula pyramidalis.—I either sow the seeds, or put cuttings from the old roots in leaf-mould and sandy peat; as soon as they are strong enough I put them off into 60 sized pots, regularly shifting them into larger sizes as the plants require them; when they have gained a little strength, I give them a rich loamy soil, well incorporated with a small proportion of bonedust; and at intervals supply them liberally with manure water. I do not find them flower vigorously under two or three years, but at that age I have had plants of both varieties, nine feet high and covered with bloom.—*J. L. Snow, Swinton Gardens.*

Large Pine apples.—In your accounts of large Pines, allow me to state that you have overlooked my father, who grew three large ones when living at Rheola, with John Edwards, Esq., Neath Vale, Glamorganshire, and which are noticed in the 1st part of the "Gardeners' Magazine," at page 453, in the year 1826. The dimensions and weight were as follows:—

July 18, 1824—One New White Providence, 11 lbs. 12 oz.
April 7, 1826—One do., circumference 21 ins., height 10½ ins., 4 gill suckers, weight 11 lbs. 14 oz.
April 10, 1826—One do., circumference 26 ins., height 12 ins., 4 gill suckers, weight 14 lbs. 12 oz.

The last two were taken from the mother plant, March 29th, 1825, and left four plants as good as those the fruit was cut from. The largest was presented to his Majesty George the Fourth.—*Richard Dixon, Dolancothe.* [We remember these Pines; but what is a Providence, *with four gill suckers*, weighing 14 lbs. 12 oz., as compared with a Queen weighing 6 lbs. 11 oz., and with no gill suckers. The Pine in question was, however, an enormous one certainly.]

Pits.—The accompanying is a plan for pits which I am about to build. My object is to have three distinct compartments of different characters, and to heat No. 3 with the radiated heat from the boiler; the Melon pit with hot-water gutters and a flue; and in No. 1, I intend having

two hot-water tanks and the continuation of the flue. This arrangement, I imagine, will be found exceedingly useful to amateurs, with small gardens like myself, and one that will require as trifling an expenditure for fuel as possible. I should have made my end pits at least 12 feet long, and the centre one 20 feet, but I am confined for space.—*A Friend to Floriculture.*

Vegetable Refuse for Melons.—Mr. Torbron states, that, when gardener to the late Mr. Knight, he prepared a bed of Oak-leaves for Melons, 5 feet high at the back, with a proper slope to the south. On this was placed a frame having 4 sashes, each 6 feet long; it was sufficiently deep to hold 15 or 18 inches of soil, allowing head-room for the plants. The soil was obtained from a meadow, which had been rendered fertile by being flooded from a river, and was mixed with vegetable ashes in the proportion of about 1 part in 30. The plants, which were of a kind then in repute, called the Salonica, were ridged out early in March, and a genial heat was maintained by means of linings. They were watered with water mixed with pigeon-dung. The fruit ripened in due time, and many of them weighed between 6 and 7 lbs. each. Mr. Knight observed that, previous to that time, he had never known one of the same kind to weigh more than from 2 to 3 lbs. One of the Rock Melon, treated in the same way, was also equally good.

Season for Repotting Plants.—Examining some greenhouse plants lately, I found that they had all made quantities of roots round the ball of the plant, and from the circumstance of these having evidently been formed after the plant had ceased growing, it occurred to me that autumn would be a better time for shifting plants than spring. It is clear that these fibres had been made when the plant was in a dormant state, and it is certain that unless they are supplied with fresh soil, the plant will not be able in the following season fully to develop its parts. The practice of spring shifting is attended with danger of breaking these newly-formed roots, and this gives a check to the plants. Plants in general should be shifted during their season of rest, for it is then they make the feeders that supply them with nourishment in the spring, when they begin to grow. Peach-trees and Vines clearly prove the assertion to be correct, for when they are forced without having had a due season of rest, the result is always unfavourable; this arises from their not having had time to form new fibres. When leaves begin to fall off, plants commence to form young rootlets, which absorb nourishment, and from these, on the first excitement of the plant, the sap ascends; fresh roots are afterwards made to keep up a supply through the season. It is necessary to keep these roots as dry as possible in winter, in order to preserve them from rotting, for if they perish the effects will soon be seen on the plants. This is an objection which many have to shifting greenhouse plants in the autumn; but if water is given with caution and the pots well drained, there is no danger to be apprehended.—*J. W. K.* [This statement is open to very considerable doubt.]

Incombustible Thatch.—It has been proved by repeated experiments, that straw saturated with a solution of lime, or common whitewash, is incombustible. This fact is of great importance to the rural population, especially as thatch is thus not only rendered fire-proof but more durable.—*J. Mc I., Hillsborough.*

Melons.—As some gardeners are anxious to grow Melons early, I beg to state that after having tried the Kew Cantaloupe and Carton's Early Cantaloupe, I find Cuthill's Early Scarlet to be earlier than either. I cut one of these here on 13th April, and another on the 27th of the same month; the latter weighed 1 lb. 15 oz., and was exhibited by H. Villebois, Esq., at the Regent-street rooms in May, 1842. I also cut the same kind of Melon last year in the second week in May, and the plants promise to do equally well this season.—*C. M'Gregor, Marham Garden.*

Edgings.—Amongst the different edgings recommended I have not seen the common Heath noticed; in a dry peat soil this is a very neat and convenient edging, and is especially useful when Box will not grow well; it has been introduced with peat with success in the gardens of the Speaker at Heckfield Lodge.—*Totty.*

Potatoes.—In accordance with the directions given in the *Chronicle*, I tried the possibility of procuring fresh Potatoes in the open air in the months of March and April. In this I was so successful, that, from tubers planted in July last, I had good dishes of new Potatoes on Christmas day, and up to the first week in February. Of these, I sent three-quarters of a peck to Norwich market, expecting a high price would be given for such rarities, but, to my disappointment, I was informed that "Sprout Potatoes would not sell!" it was said, they were of too dark a colour to be new Potatoes. How is this to be remedied? they are fair as May roots, when properly boiled.—*M. G.* [Will any of our correspondents answer this?]

Icehouses.—As there was much discussion on the different kinds of Icehouses last year, ask your correspondents to give us their experience as to any they constructed. I thatched a large mass of ice in a sloping bank and well drained it; but either from the soil being damp, or from some undiscovered defect in the thatching, it was all melted in the early part of May. We have had no account of what success your readers had in the cultivation of the Courge courcelle.—*Totty.*

Societies.

ENTOMOLOGICAL SOCIETY.

Monday, Feb. 5.—H. Newport, Esq., President, in the chair. Messrs. Spence, J. E. Gray, Yarrell, and Waterhouse, were announced as having been elected Vice-Presidents, and Mr. Newport re-elected as President. Mr. Rich exhibited several species of the large Beetles of the genus Goliathus: amongst them were G. Druræi, G. polyphemus, and others. Mr. Bond exhibited a specimen of Pontia Rapæ, which was taken alive during the past month. Mr. Doubleday exhibited several Lepidopterous insects from Mr. Barnes' collection of North American insects, and pointed out the identity of several forms with British species, and others closely resembling British forms, although specifically distinct. The President exhibited a living specimen of Hypæna rostralis, which he had kept in his possession since September last, and which during that period had had no food. M. Des Vignes described

several species of Lipterous insects in the late Mr. Barnes' collection, which were indigenous to Great Britain. A paper was read from Professor Erichsen, of Berlin, describing several species of the genus Paradiseus, belonging to the Lamellicorn group of Beetles. A letter was read from Dr. Savage, giving an account of some Goliath Beetles, which he had collected: amongst these were two pairs of the G. quadrimaculata, and a specimen which Dr. Harris had pronounced a new species, closely resembling G. polyphemus. A description of some species of Leucanidæ was also read from M. Guerin Menéville. The Secretary read a letter from Mr. Melley, in which that gentleman had made some inquiries with respect to the insects that attacked the excrement of domestic animals that was used as a manure. He wished to know what species of insects attacked the excrement. Whether their attacks were prevented by spreading it immediately, and whether any advantage was gained by placing the excrement in water and then spreading it, and with regard to insects that attacked the roots of plants, whether they could be destroyed by irrigating the crops which they attacked. Mr. Westwood said that, in reply to this letter, he had stated that the species of insects which attacked the excrement of animals belonged to the families Geotrupidæ, Staphylinidæ, and Sphæridæ; that it was probable they consumed but little of the manuring principles of the excrement, and that irrigation would probably fail to affect insects that attacked the roots of plants. A long discussion followed, in which Messrs. J. E. Gray, Walton, Marshall, Westwood, Waterhouse, and the President, took part, from which it appeared that insects might consume those principles of excrementitious matter, which were of importance to plants, as food; that, as long as insects were destroyed in the larva state, this was of little importance, but that if allowed to attain their perfect state, the manuring power of the excrement would be reduced; and that the best way of preventing the attacks of insects was as quickly as possible to collect the excrement of animals into heaps, as insects only attacked the surface. Mr. Waterhouse remarked, with regard to applying water for the purpose of destroying insects, that this would be more effectual in the perfect and larva state of the insect than in the pupa state, and thus the season at which water was employed would be of great importance. The President announced that the Rev. Mr. Hope had offered two prizes of five pounds each for the two best papers—the one on vesicatory insects, and the other on a subject not yet named.

Reviews.

An Inquiry into the Nature of the Simple Bodies of Chemistry. By David Low, Professor of Agriculture in the University of Edinburgh. 8vo. 1844.

The science of Chemistry is generally considered to be purely experimental, because though every new fact adds to our store of knowledge, and brings us nearer to the comprehension of those forces which regulate the transformation of matter, yet it is wholly impossible to argue from the known to the unknown; *à priori* reasoning has no weight with the Chemist, and though theory may be useful to guide him in experiments, it must never be permitted to bias him in the conclusions he draws from facts. The work of Professor Low is an attempt to establish a new chemical theory, "that all so-called simple bodies are compounds of oxygen and hydrogen;" but it is unsupported by experimental evidence of any kind. Chemists are in the habit of terming those forms of matter which they are unable to resolve into simpler substances, *elements*; and the term is correct, inasmuch as they are the elements of other substances. But it certainly does not follow that they are not compounds themselves. Nevertheless, so long as we do not know of what they are composed, or how to prove that they are compounds—in short, until we have experimental evidence of such being the case, we are not justified in regarding them as compounds, even though we may think it very probable that they are. Professor Low's arguments are ingenious, but they are those of a metaphysician, and not of a Chemist. He has followed out in part the views of Dr. S. Brown, with regard to the possible existence of the same kind of matter in different forms, and possessed of different properties. Much more must be done in Chemistry before such generalisations can be usefully made. It would be easy even now to make many theories as to the possible composition of the so-called simple bodies quite as satisfactory as that of Mr. Low, but we doubt whether it would at all advance the science. Facts, not theories, are wanted; and if we do form theories, they must be founded on facts; whereas the speculations of Professor Low are founded wholly on theoretical views.

Miscellaneous.

The Franconia Raspberry—its Hardiness, and its Value as a Forcing Variety. By A.—This shrub has been cultivated at Salem, in America, for several years: the first winter they were covered; the second year one half of the plants only were protected. Those left exposed to the winter bore as well, if not better, than the protected ones, and appeared in perfect health the summer following. This year the bed contains about one thousand stems, after pruning out; every one in sound condition, and wholly exposed to the winter, which has been a very trying one. Other beds, in different locations, were left unprotected the past winter, and have proved perfectly hardy. If it is unnecessary to protect them, there is a saving to labour in spring and autumn, seasons of the year when gardeners are very busy. Any one in the country cultivating them by thousands, can the next winter leave a part, in an exposed situation, unprotected, and prove the thing. It may be that the protection afforded by houses in the city may be sufficient, and the plant be killed in the open field. They also force well. I tried a few pots of them in the greenhouse, last winter, with different treatment. The result was in favour of those grown in the greatest heat, with a dry atmosphere, and watered with carbonate of ammonia, in the proportion of three hundred parts water to one of ammonia; next, those watered with liquid manure; and last, those watered, simply, which were nearly a total failure, the fruit not swelling off. They were taken up with a ball of earth, before severe frost, and all put in same sized pots, with as much rich soil as could be added.—*Hovey's Magazine of Horticulture.*

China.—Advices have been received from Mr. Fortune, engaged in collecting seeds for the Horticultural Society in China, dated Chusan, Nov. 12. He describes the whole coast of China to the northward as consisting of bare rugged rock, barren sand, and burnt gravelly clay, but with beautiful plants here and there. He had met with very bad weather in his passage to Amoy, but had had an opportunity of exploring the islands of Koo-long-soo and Amoy. On the voyage thence to Chusan, the vessel encountered heavy gales in the Formosa Channel, and was twice driven back, once to Chinchen, and once to Chameo; this, however, gave him the opportunity of landing at those places, and exploring the country for several miles inland. On no occasion had he met with serious obstacles to penetrating the country, but, on the contrary, found the natives particularly civil, much more so than on the coast further south and at Canton. Mr. Fortune had fallen in with hills covered with Azaleas, and with several other good things, seeds of which, in very small quantities, were inclosed in his letters. In particular, he had met with a very beautiful Buddlea, with rich purple flowers, arranged in clusters like a Lilac; and a very fine Campanulaceous plant, with flowers as large as those of Lisianthus Russellianus. What he had seen of China gave him great hopes of fully realising the anticipations of the Society. He was about to proceed to Shang-Hai and Ning-po.

New Zealand Resin.—Dr. R. D. Thomson has published an account of the resinous exudation of the Cowdie Pine, from which it may be inferred that it deserves attention as an article of import. It is a very hard transparent substance, in the state in which it arrives in England, and has long ago appeared to us likely to prove valuable as an ingredient in varnishes; but it was found difficult to dissolve it. Dr. Thomson has, however, ascertained that it may be dissolved in hot *absolute* alcohol and in oil of turpentine.

Mexican Poison, Guaco.—Dr. Uslar, of Oajaca, in Mexico, states in a letter that he has investigated the nature of the celebrated Mexican poison, Guaco. He speaks of its medicinal properties as powerful, and hopes European physicians will investigate its powers. He is of opinion that the plant which produces the poison is a species of Convolvulus, and not the Mikania Guaco, as is usually supposed. He doubts altogether the active properties of the Mikania, which also accords with Hancock's opinion.—*Bot. Zeit.*

Lemons—Himalayan method of Keeping.—"Five dozen Lemons were bought in the bazaar (Srinagur) for about fourpence; six of them, taken indiscriminately from the basket, weighed about five pounds. It is customary to pluck the fruit when it has attained its full growth but is not quite ripe. It is then buried in deep holes in the ground, lining the pits and covering the fruit with dry leaves. In this situation it attains maturity, and if not bruised in packing, retains its form and freshness for a considerable period. I saw some disinterred, after they had been buried for three months, and they were in the most perfect preservation."—*Moorcroft's Travels*, vol. i. p. 55.

CALENDAR OF OPERATIONS

For the ensuing Week

I.—HOTHOUSES, CONSERVATORIES, &c.

Many plants will soon be fit for repotting. When plants are removed to a higher temperature, examine their roots, and see if they are healthy, and if not, shake the old soil from them, and repot them in fresh soil into smaller pots; this is a good mode for preparing plants for the one-shift system, which may be adopted as soon as the roots begin to spread on the outside of the new soil. The one shift should never be adopted until you are satisfied that the roots are in a healthy state and beginning to grow. There is no time when a low night temperature is more necessary than during the next six weeks, as plants are now more easily excited than at any other period.

Conservatory.—Orange-trees, if now removed to an early Vinery or stove, and kept in doors all summer, will come into flower next Christmas with very little forcing. Camellias that have not formed flower-buds may also be introduced into heat in succession from this time; some of them may be expected to flower about the middle of next September. I had some treated thus last year, and they began to flower at that time. Plants of the Fuchsia corymbiflora which were cut back last autumn to the ripened wood, and preserved in any outhouse through the winter, will flower in May if they are now removed to a Vinery or forcing-house. The night temperature of the Conservatory should now be lower than through the winter, say about 40°, in order that the plants may be started away slowly at first; this should be attended to now by all who regard the proper cultivation of their plants.

Greenhouse.—If you guard against frost, there is no danger of this house getting too low in temperature, and air should be freely admitted every fine day, in order to keep the plants from growing too rapidly at this season. Owing to a drier atmosphere being thus produced, the plants in this house will require constant attention with regard to watering.

Forcing pits.—That variety of the common Lilac called Charles the Tenth is the best of them for forcing, as it retains its high colour better than the Old Purple one; and if it was grafted on the Persian Lilac it would check its vigorous habit, and render it more manageable as a pot plant. Has the Double Sloe been submitted to forcing by any one? It would make a good contrast with such plants as the Double Dwarf Almond and the Double Chinese Almond, the Rhodora, &c., all of them flowering before their leaves appear. About the same treatment as that for forcing Peach-trees will suit them; and, being naturally early bloomers, they are good plants for forcing. A steady bottom-heat, a moist atmosphere, and attention to cleanliness, are the chief requisites in early forcing flowers.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

As soon as the ground is a little dried it will be a good plan to have all the vacant beds in the flower-garden forked over, so as to get the soil properly pulverised prior to planting out the autumn-sown annuals. Preparation must also be made for a general sowing of the more hardy kinds, such as Larkspurs, Godetias, Clarkias, Nemophilas, &c., which should be got in the first day the ground is sufficiently dry to admit of sowing them. Proceed with the pruning of Shrubs and common Roses, but leave the more tender kinds until you are sure they will not be injured by frost. The most tender of the Chinese varieties, that were covered in autumn with leaves are in excellent condition, and I expect to carry them through the winter without losing a twig.

Reserve Garden.—See that the plants in this department are not thrown out of the ground by the late frost. If they are loose fasten them. Proceed with planting out biennials as soon as the ground is in a fit state, and prepare a little ground in a warm corner for sowing Stocks and some of the best of the annuals for transplanting.

Pits and Frames.—Here there will be no want of work for the next three months. Some of the Stocks and other annuals sown some weeks back will require potting off, putting 3 or 4 plants in a pot. Put off Verbenas, &c., put in cuttings of all kinds which you are deficient in. Divide and make root-cuttings of Bouvardia triphylla and angustifolia, and get the plants forward and strong for planting out. Put Salvia patens into heat to produce cuttings, and see that everything is in order for the spring, which will soon be upon us.—*W. P. A.*

III.—FLORISTS' FLOWERS.

As a matter of course all Floricultural Calendars must to a certain extent be acted on only as the weather is favourable for the operations there detailed as necessary. During spring and summer, the experienced Florist finds it comparatively easy to point out the previous week what is requisite to be done the ensuing one. But at this uncertain season we must be guided by circumstances. Whilst writing, the frost appears to be rapidly disappearing, it will therefore cause the Florist to be on the alert, and if the weather continues mild, draw the lights completely off the Auricula frames during the day, examine the plants minutely, and see that all is going on well. Should any mild rain fall during the week, they will be benefited by a good sprinkling "*in the middle of the day*;" when the lights are drawn on till them, so that the grass may get as dry as possible before night.

Carnations.—The same observations will apply to these flowers and carefully remove all spotted or diseased leaves.

Tulips.—Still cover with sand as they appear.

Ranunculuses.—Should the beds get sufficiently dry, they should immediately be planted; we usually plant two very large beds, one in about ten days or a fortnight after the other; this gives a competing Florist a better chance, besides prolonging the season of bloom in his garden.

Dahlias.—Still strike cuttings in moist heat as they get long enough.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—Where Pines are extensively grown, it would be inconvenient to examine and repot them a few at a time, as they want it; and as the plunging material will now require some addition to keep the bottom-heat to between 80° and 85°, it will be better to have a general arrangement of the whole stock of successions in pots whenever the weather is favourable. Those Plants intended for fruiting in the autumn should be carefully examined, and if the roots are not healthy, or the soil has become close, a partial or entire removal of both, as may appear requisite, should take place. In repotting, the size of pot must be determined by the sort of Pine and condition of the plant. The Montserrat, Jamaica, and some others, make fewer roots than the strong-growing Providence, Enville, and Queen, and consequently require less pot-room. If it is intended to plant them out as soon as it is ascertained that the fruit is formed, smaller pots may be used than if the plants had to mature their fruit in them. In potting, use some Moss over the drainage, and sprinkle a handful of soot over the Moss, to keep out worms. Those of the younger successions that are in good condition at the root should have a good shift, as they will fill a large pot by Midsummer, and the less they have to be shifted, the fewer checks they receive. If the heat in the bed at a foot from the surface is about 80°, do not use much fresh material, as the heat from the sun will soon begin to act upon the bed, and it will be better to have to add a little more round the outside pots in a month hence if necessary than to run any risk of injuring the roots by an over-degree of bottom-heat.

Vinery.—From the time the fruit-bearing shoots are far enough advanced to be stopped, the temperature should be fully 75° by fire heat during the day, letting it fall towards evening, and keeping it as low as 60° during the greater part of the night. This treatment of the Vines should be strictly observed, as they will be more healthy from it, and the crop about as early as if a higher night temperature were kept, and it will be found more economical. The Vines grown in Pine-stoves, and indeed in Vineries also, will be benefited by tying Moss round the old wood, as it will keep them moist and cool, and the sap-vessels expand better than when exposed to dry heat.

Peach-house.—Where the fruit is swelling, the night temperature should be about 60°, and 65° to 75° during the day, by fire-heat. Give air when the sun raises the thermometer to 80°. Careful attention to temperature and syringing will, in most cases, keep down insects; but where this fails, fumigating should be had recourse to. The most effectual way of destroying green-fly by fumigating is to fill the houses moderately on two successive evenings.

Cherry-house.—If the Cherries have set numerously, and are so far advanced as to show which are the most promising fruit, thin out the smallest. Weak liquid manure may now be given with advantage to the plants in pots.

Melons.—For a moderate-sized frame, one plant under the centre of each light is sufficient; but if two are preferred, plant them 15 inches apart lengthways of the frame. In preparing for planting out Melons in pits of a good width, it is better to put the plants within 12 inches of the front-wall, and train them on a trellis towards the back, 2 feet from the glass. Fill the pit to within 3 feet of where you intend the surface of the mould to be with tan or leaves in a fresh state, then lay 6 inches of decayed leaves and dung upon it; then form a ridge along the front of turfy loam, with a portion of burnt marl and charcoal for turning out the plants upon, leaving the remaining space to be filled up at intervals. The plants, when turned out, should be 2 feet from the glass.—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Grafting.—Where there are inferior sorts of Apples and Pears, or too many of one sort, procure scions of superior varieties, and keep them till wanted in a cool situation.

Cucumbers.—Sow seeds, or procure a few plants from those who force early. A Cucumber that grows quickly, fruits plentifully, and eats crisp, is to be preferred, where exhibition is not an object. The temperature should range from 65° to 75°, allowing 5° more for sun-heat. If the condensed water on the sashbars is of a pure colour there will be no danger from rank steam.

Celery and Cauliflowers.—Sow in a slight hotbed; the latter to succeed those sown in the autumn. A pot of Celery may be put into the Cucumber frame, as a little will require to be sown thus early if fine heads are expected in September.

Potatoes.—Plant in frames, and forward tubers by putting them in any warm place, for planting under straw covers and hurdles.

Peas and Beans.—A sowing of these will require to be made as soon as the weather will admit.

Hyacinths and Gloxinia, if not done in the autumn, should now be planted the first opportunity, digging the ground deeply, making it fine and just fastening the bulbs on the surface.

Cabbage.—Where there are not plenty of autumn-sown ones, now sow on the warmest border you have, or in a carrot-frame.

Onions and Carrots.—The ground intended for these cannot be too often turned after sharp frosty mornings.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Attend to former directions respecting the work that is necessary to be performed. It would show care, and add much to the beauty of trees if all rotten branches and split boughs were removed, and evergreen shrubs planted under the trees; young Firs, such as Silver, Spruce, and Hemlock-leaved Spruce, *to be headed off at a proper height, might also* be planted as underwood; this may be done by having a cart filled with good rich compost, mixed with leaf-mould to put over the roots when planting. By this means most kinds would succeed, and render the woods much more cheerful in winter.

Coppice.—Forward all necessary works when the weather permits. Having omitted formerly to mention the distances from each other at which Coppice-wood should be planted, I would recommend planting them at about four feet apart each way, as it will be advisable to have plenty of stools to choose from, as some will grow faster than others, and some may fail. In forming a new Coppice, I would prefer planting in masses, each kind by themselves, according to the soil and locality. They would have a better appearance, and it would prevent some kinds from overgrowing others and injuring them, besides it would be more convenient, when cutting, to have each kind separate. I also omitted to mention Birch, and some kinds of Willows, as being very profitable and useful copse-wood, along with Oak, Ash, Hagberry, or Bird Cherry and Hazel, as being the most useful. I may also venture to recommend the Locust-tree in favourable localities. The Hazel might be mixed with tall-growing trees, to draw them up to a greater length.

Young Plantations.—Too much care and attention cannot be bestowed upon these during the early periods of their growth, for all their future value depends upon this. A few trees will naturally take the right way, having a proper proportion and equality of side-branches, with only one leader, but for one of these there are scores that require timely and skilful training to keep them in right order.

Hedge Rows.—It is much to be regretted that there is so little attention paid to the proper training of trees in hedge-rows, which might be made useful and ornamental if a little care was bestowed upon them.

Nursery Work.—As the weather continues unfavourable for many operations in this department, all works that can be forwarded with advantage should be proceeded with, to be ready for the more active operations of planting and sowing, when the weather becomes more favourable.—*W. B.*

State of the Weather near London for the week ending Feb 15, 1844, as observed at the Horticultural Garden, Chiswick.

Feb.	Moon's Age.	Barometer. Max.	Min.	Thermometer. Max.	Min.	Mean.	Wind.	Rain.
Fri. 9	9	29.185	29.164	44	32	39.0	W.	.06

Sat. 24	46.5	34.7	40.6	9	0.20	—	1	4	2	4	—	2	3

The highest temperature during the above period occurred on the 30th and 31st, 1841—thermometer 58°; and the lowest on the 9th, 1840—thermom. 19°.

Notices to Correspondents.

Our Correspondents will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

Communications from the following Correspondents are in type, and are only waiting till room can be found for them:—*M. G., J. B. K. L., Nemo, J. Wighton, A Practical Man, Peter Mackenzie, Martin Doyle, A Bee Preserver, C. A. A. Lloyd, G. Thompson, W Billington, O., Vitis, Q., J. Spencer, R. Erring. Sen., Gr., J. M. L.*

Agrostis Spriatus.—*Proteus.*—This plant is a native of Brazil, and produces its pretty bell-shaped flowers, of a bright yellow strongly veined with scarlet, for ten months in the year. It likes a moderate supply of water when growing. The temperature for it may be that of the open air in summer—about 75°, at most. The kind of soil to grow it in is not important, but it must be allowed to have plenty of pot-room for its roots, or it loses its leaves at bottom, and becomes naked and unsightly.‡

Charring.—*O.*—Soda put on a hotbed, and sticks inside it, may be greatly reduced, but cannot be considered charred by any such operation.

Deodars.—*Georgn.*—Place cuttings of the half-ripened wood with the points cut off, under a handglass, in a very little bottom-heat, and they will strike root.

Emigration.—*A Poor Cabbage* will do better here in a comfortable place than in the United States or anywhere else. We do not admire the land of repudiation, and cannot recommend any one to go to a place where swindling is the national characteristic. If *Cabbage* is in such a state of fermentation that he cannot remain as he is, then he had better try Canada or New Zealand, provided he has some money, some patience, and a great deal of energy. Any place, however, is better than one where you have a large garden, 1400 pots, 140 succession Pines, 120 fruiters, Peach-house, Vinery, pleasure-ground, and kitchen-garden, with only one man, who is often absent six weeks at a time. If there is such a place, we can only say that the master ought to be his own slave; and if gardeners would take our advice he should be so.

Exhibitions.—*An Exhibitor.*—It is rather a nice point whether Clematis Sieboldii and azurea grandiflora can be called greenhouse climbers or not. They are certainly hardy, but they thrive much better in a greenhouse than out of it. You had better inquire of the secretary what the practice is of the Society where you propose to exhibit.

Florists' Flowers.—*Warwickshire.*—Your Chinese Primrose looks like a half-bleached variety of the dark-red notched kind. The specimens are much withered; possibly as there are very few varieties at present of this plant, that you have sent may be worth keeping.

Pharmaceutical Journal.—*Oliver.*—Your question should have been addressed to the "Pharmaceutical Journal." According to the archives of Pharmacy, a sweet fumigating inflammable fluid is prepared by mixing together 48 oz. spirits of wine, 4 oz. Tinct. Benzoin, the like quantity of Tinct. of Vanilla, of Acetic Ether, and Oil of Bergamot, each 1 oz.; 2 oz. Oil of Cedar, ½ oz. of Tincture of Musk and of Peruvian Balsam; Oil of Mace, Oil of Cloves, and Oil of Cassia, each ¼ an oz. We cannot again answer such questions as this, which have nothing to do with the subject of our Paper.

Gherkins.—*J. B. K. L.*—The little prickly Russian Gherkin is often used in pickles, and it is always distributed by the Horticultural Society; but, from the description given by a late correspondent, we suppose that he meant the Cucumis prophetarum, a bad material for such purposes. C. Anguria is also used in the same way, but is equally objectionable.

Heaths.—*Dianthus.*—These are best struck early in autumn, but they will do now. Put them in silver sand under a bell-glass, and wipe it out every morning and evening. We never saw cuttings of forced Pinks used, and should doubt whether the practice is worth attempting.

Hawker's Licence.—*W. K. I.*—Garden seeds cannot be carried about the country and sold from door to door without a hawker's licence. Every hawker, pedlar, &c., must pay a duty of 4*l.* for each year; and if he travel with any horse, ass, mule, or other beast drawing burthen, the additional sum of 4*l.* yearly for each such beast.

Holly-berries.—*A Subscriber.*—Of your Holly-berries that were mixed with sand and buried this winter in the ground, if sown in March, a few may come up during the summer; but they will not grow, generally, before next season.‡

Insects.—*A Subscriber's* Scales from the Peach-tree appear to be the Coccus pateliformis—*Gard. Chron.*, vol. iii., p. 517; the smaller ones running about are the young of the same, but it is very probable that a smaller *species* may also infest the Peach-tree. *R.*——*O.*—We doubt whether guano sprinkled among compost will kill wireworm.——*J. D.*—No. 1 is closely allied to the Coccus Testudo, of Curtis, and thus are probably identical; 2, is a Lepisma, but I neither know the species, nor can I say upon what it feeds; 3, is Aspidiotus Bromeliæ, of Curtis; 4, is a young Helix; 6, the leaf has probably been punctured by an exotic Thrips. The box No. 5 was crushed and empty. Pill-boxes, unless cut down and well made, will not bear the pressure by post, and the stamping at once destroys them. If a pill-box be cut down to the depth of half an inch, and a slice of cork of the same thickness, but very much smaller, as the cork of a vial, be stuck in the centre with sealing-wax or a wafer, the lid and bottom will not sink in, and there will generally be plenty of room left round the cork for specimens; for the same reasons nothing can be worse adapted for transmitting fragile or living objects than lucifer-boxes, which are often employed. For small insects the barrel of an old pen or a quill stopped at both ends with cork, is an admirable protection per post. As the period is now approaching when we expect to be favoured with numerous specimens both from the Gardener and Farmer, we hope our recommendations will be adopted, that specimens may arrive safe, and enable us to give satisfactory answers.—*R.*

Lawns.—*F. R. S.*—A good kind of Grass for improving a lawn is Crested Dogstail; it may be sown in March. The common practice is to bush-harrow the lawn in order to stir up the soil a little for the seed, which should be sown broad-cast when the ground is damp, passing a garden roller over it when the ground becomes sufficiently dry.‡

Luculia gratissima.—*Rhodon.*—This is an excellent Conservatory plant, but we never saw it tried in a window; it succeeds well in a mixture of turfy loam and peat. It may be propagated by cuttings, which require bottom-heat.——*W. C.*—It is not a climber, but a beautiful greenhouse shrub, with large fragrant blossoms, having some resemblance to those of a Hydrangea.‡

Manures.—*Ignoramus.*—Charcoal seems useful for everything; the softer it is the better. We know nothing of the action of Potter's liquid guano; but his common guano is no very good that it is worth trying the other. Nothing that we have seen acts on Pelargoniums like superphosphate of lime.——*O.*—We never heard of Rushes being used as manure for Auriculas. Bran, soaked with soapsuds, which has lain two years or nearly, although not reduced to a soil, is fit for use. Kill the small dingy-coloured worms, by moistening it with boiling water.——*A Lady.*—Nitrate of soda is no doubt useful to greenhouse plants if mixed in the water used in watering them. The weaker the solution the better. Instead of 2oz. to 6 gallons of water we should only use half as much, or even half that, and trust to the quantity that will be given by slow degrees. A much better material is Potter's guano or superphosphate of lime. If you love your plants they will take it kindly of you to give them some.

Morphology.—*E. B.*—We are much obliged for your very sensible letter; but we make a point of not coming into contact with such people as those to whom you allude. It is true that the criticism is "a production which for egotism, ignorance of the subject-matter in dispute (!), and illiberality, cannot be paralleled in the whole range of English literature," and for that very reason it is beneath even contempt.

Names of Plants.—*Cork.*—If you will again refer to p. 71, you will see that the account of Statice rytidophylla is a mere extract from the "Botanical Magazine," with which we have nothing to do. Your leaf is surely not it, but seems to be S. oleifolia, or some such species. S. Dicksoni, or Dickensoni, is in the way of S. arborea, and is the same as S. rytidophylla.——*O. B.*—1. Cineraria Tussilaginis var.; 2. Erica gracilis; 3. Indeterminable; 4. Ditto: perhaps Bignonia pandorea; 5. Lavandula dentata; 6. Indeterminable. Plants out of flower cannot often be named with any accuracy.——Δ.—One of your Begonias is coccinea, the other has no good flowers, and we do not recognise it; the plant called Hibbertia is Pomaderris elliptica.——*W. M.*—Your Gesnera, which looks like a cross between G. Douglasii and bulbosa, is handsome and new to us.——*S. H.*—1, Carex fulva; 2, Scirpus sylvaticus; 4, Blechnum boreale; 5, Asplenium ruta-muraria; 6, A. adiantum nigrum; 7, Polypodium vulgare. ‡——*Tropical.*—Next week.

Oaks.—*Crustyman.*—There is no good reason to suppose that Wainscot Oak is produced by the Quercus Cerris. It is probably the wood of Q. sessiliflora run up in the close forests of the Continent.

Peach-trees.—*A New Subscriber.*—Your Royal George Peach-tree has been planted in soil too highly manured. You must manage it in summer in such a way as to have no occasion to cut out over-luxuriant shoots in winter. Much cutting will increase the tendency it has to gum and canker. Withhold manure from the border till such time at least as the tree begins to bear.‖

Pea.—*A Subscriber.*—The Pea you sent of the variety which grows with you to the height of 9 ft., and which you say is the best tasted of any you have ever met with, continuing in eating when other Peas are hard, is Knight's Tall Marrow.‖

Pears.—*J. W. T.*—On your three worthless Pear-trees on a north wall, you may graft for fruit to come in between January and March, Hacon's Incomparable, Ne Plus Meuris, and March Bergamot; but early varieties are more appropriate than late for such a situation. Grafts from the garden of the Horticultural Society cannot be obtained except by Fellows of the Society.‖

Pine-apples.—*X. Y. Z.*—We do not advise you, as a novice in Pine-growing, to attempt them out of pots. Try that way first, and when you have become acquainted with their pot management, then turn them into a bed of earth, warmed by hot-water gutters. Soil is of less consequence than good management. See what is said on this subject at p. 19, of the present volume.——*J. B. K. L.*—The instance you mention is noticed to-day. It, however, was not a Queen Pine, but a Providence, which is a very different thing.

Pits.—*An Irish Economist.*—Mr. Paxton's plan of a pit is only for its construction and not for heating it. It need not be heated at all, or it may be warmed in 20 different ways. Our columns have, of late, been occupied by descriptions of heating, all of which are, no doubt, more or less good. Will none of them suit you? We fear clay pipes will not answer. Some say they do, but in our experience they do not. We cannot give plans of boilers; that is the business of those who sell them. Rogers's conical boiler is a truncated hollow cone.

Polyanthus.—*O.*—The florists who use for these flowers the soil in which Cowslips grow, do so upon the supposition that plants know better than we do what they like; and no doubt florists are right. The Polyanthus and Cowslip have exactly the same habit and constitution.

Potatoes.—*Argles.*—Lime is a good manure for Potatoes. If you can get lime-rubbish, so much the better. We should give the land a good dressing—say 20 loads an acre of lime now, and stable-dung at the time of planting. You would no doubt, however, find your account in using a few bushels of Potter's guano instead of lime. It costs more, but produces more! and then you may sell the stable-dung.——*Ignoramus.*—Nothing will make Potatoes mealy that are grown in the shade. They *must* have light, and plenty too, if they are to be of good quality.

Potted Plants.—*O.*—When pots are lined with moss the young roots are entangled in it, and hold the soil together, so that shifting may be easily accomplished. Or, if sphagnum moss is employed, it keeps the soil damp. Half-decayed woollen rags would probably be useful in potting, but we never saw them tried.

Pruning Forest-trees.—*Dendrophilus* will appear shortly. We have already so fully and repeatedly expressed our own opinion on this subject that we cannot undertake to renew it again speedily. Col. Greenwood's new book will, however, probably lead to some discussion.

Raspberry.—*T. P.*—We will inquire.

Stakes.—*Midland County.*—Point and char your Larch poles, by all means, before you drive them. But did you not see what was said in our last Number about Seyssel asphalte for this purpose? There is no object in putting them in round. If driven close together, and secured by a lath nailed to the top, they make the best of all hare-proof fences.

Sugar-bakers' Scum.—*Opus.*—We regret to be unable to give you any information concerning the action of this substance. It is reported to render Grass very rank, which is quite in its favour; and it is said to be good for Turnips; but we can get no satisfactory intelligence upon the subject. Our correspondents would much oblige us if they could furnish some information respecting it.

Timber.—*E. H. L.*—Larch-poles, of 6 inches average diameter at the largest end, are worth about 2*s.* 6*d.* each in London, Good Oak is worth from 5*d.* to 7*d.* a foot superficial in the inch, which must be what your sawyer means, and not 4*d.* a foot for the ¼ inch. English Oak is worth from 6*l.* to 8*l.* per load, according to quality. We will take measures in a week or two to publish the London prices of English timber, and continue to do so from time to time.

Vines.—*G. M.*—Having two small Vineries to furnish with 7 plants each, you may plant in the early one, 3 Black Hamburgh, 2 Royal Muscadine, 1 White Sweetwater, 1 Black Prince; in the late house, Black Hamburgh, 2 Charlesworth Tokay, Muscat of Alexandria, 3 St. Peters. For fruiting in pots, Black Hamburgh and Royal Muscadine. ‖——*A. B.*—It will be advisable to manure your Vine-border with superphosphate of lime. Let the roots be kept dry in winter, but moist in the growing season; the reverse of this is most probably the cause of failure as regards your crops of fruit. If in consequence of its being situated near the house, you prefer having the border neat and rather gay during the summer, you must select such plants as will neither root deeply nor overspread the surface, and they should be thinly planted.‖——*Emily.*—A fall of 18 inches on a width of 4½ feet will be quite enough for your verandah, especially as you intend to have it glazed with British sheet-glass; and if you do so, there will be very little risk of damage from hail storms. Vines will succeed if planted to grow up the supports in front, and trained under the glass. For this situation, the Black Hamburgh and the Royal Muscadine are most suitable varieties.‖

Vines in Pots.—*Peter C.*—Vines for early forcing may be coiled once round with some advantage, because a store of perfectly-elaborated juices is contained in the mature wood; which will prove useful in forming leaves in the first instance. But it must be borne in mind, that if a great length of wood is coiled in the pot, a large portion of the returning sap from the recently-formed leaves is appropriated by such great bulk of wood, and the latter gains an accession of tissue from that which would otherwise have gone to the formation of fresh roots. The Canes should be potted in January, and brought gradually forward, so as to break the buds before March, when sufficient light will be obtained for the expanding foliage; after which there will be a long enough season to prepare them for fruiting next summer.‖

Whitney's Transparent Fluid.—*X. Z.*—The following is Mr. Whitney's answer to your inquiry:—"The calculations I made, and which I still adhere to, was on *glazed calico*, which I have found to take as nearly the quantity specified as possible; but I find that different materials require larger quantities of the composition to render them waterproof. Book muslin takes considerably more than glazed calico, as all the compartments of that thin fabric must be filled up. Very thick calico without glaze also takes more to saturate it, for which reason I have particularly recommended that parties should use glazed calico, and apply the composition on the side *not* glazed. Your correspondent must have omitted to read the directions, or he would then see that the composition is to be put on *hot*. I have no doubt, however, that when his calico is dry it will be perfectly impervious to moisture, and I should be inclined to let it stand the summer, and give it a coat in autumn, if to remain out all the winter."

Miscellaneous.—*T. S.*—We know of no proportion for mixing oil, &c. for white paint; your own observation will tell you when it is of a proper consistence. If yours rubs off like whitewash, it may be because you use bad oil; but it is more likely to arise from using bad white-lead, which is often adulterated with common whitening. Get good materials, of respectable people, who do not profess to sell cheaper than they can buy, and your paint will be as good as your neighbours'.——*J. B.*—You may plant a Pyracantha, or a Chimonanthus, or a common Laurel, or an Alaternus, or a Phyllirea. We should plant the first. Violet-seeds cannot be readily bought. Why not get the wild sorts out of the woods? none are sweeter. They may be planted now, and will blossom soon; but we doubt if they will succeed. Better try Periwinkle and Lilies-of-the-Valley.——*Uckfield.*—We are in possession of an answer to your question from "O." that will be forwarded to you upon your giving us your real name and address.‡——*R. L.*—Address, "The principal Superintendent of the Gardens, Hampton Court."——*Eats.*—A book is at the office for "Eats."——*Alpha* will find directions for the management of the Tuberose given at p. 149, 1843. ‡——*Theta.*—We do not know where seeds of the Sirdar Melon may be had. Your letter is sent to Mr. Fleming. ‡——*A Constant Reader.*—The term struck hive in the article on Bees was misprinted for stitched hive, or the hive with sticks in it. Your other questions will be answered by Mr. Pettigrew himself, to whom your letter is sent. ‡

Erratum.—Feb. 3, p. 70, Polyanthus—for "pin-eyed" read "pin-eyed."

*** As usual many communications have been received too late for answering this week.

EXAMPLE FARM.

WANTED, to Rent on Lease, for a term of not less than 21 Years, to enter at Lady-day, a Commodious Dwelling-house, and about 120 acres of Arable Land, for the purpose of forming it into an EXAMPLE FARM. It must be near to a Railway station, and within 50 miles of London; on the greensand formation, under the chalk, or on the London clay or plastic clay above the chalk.—Apply to Mr. Morton, Chesterhill, Stroud.

AGRICULTURAL SCHOOL.

MESSRS. NESBIT'S ACADEMY, 38, KENNINGTON LANE, LAMBETH, near London.—"From Chemistry alone further progress in Agriculture is to be expected."—Liebig. In this school, in addition to the general routine studies, every facility is afforded for the acquisition of a sound knowledge of Chemistry. The pupils are *practically* taught in the laboratories, the methods of analysing the various earths, soils, manures, &c.; and likewise the means of detecting the substances abstracted from the land by different crops. Land Surveying is also taught practically, as well as theoretically. A copy of a lecture on Agricultural Chemistry, delivered by Mr. J. C. Nesbit to the Maidstone Farmers' Club; and the terms of the school, which vary from 40 guin. to 70 guineas per annum, may be had on application, either personally or by letter.—Mr. Nesbit's Works on Land Surveying, Mensuration, Gauging, Arithmetic, English Parsing, Education, &c., may be had of all booksellers.—References: Dr. D. B. Reid, F.R.S.E., &c., Author of "Elements of Practical Chemistry," &c., St. James' Park, Westminster; G. F. Richardson, Esq., F.G.S., Author of "Geology for Beginners," &c., British Museum, London; W. and J. Gibbs, Esqrs., Civil Engineers, Devonshire St., Portland Place, London: Rev. T. Duffe, Carlisle Episcopal Chapel, Lambeth; R. Greenhill, Esq., Ashford, Kent; and C. G. Whittaker, Esq., Barming, near Maidstone Kent.

The Agricultural Gazette.

SATURDAY, FEBRUARY 17, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Feb. 21 . Agricultural Society of England.
Thursday, Feb. 22 . Agric. Imp. Society of Ireland.
Wednesday, Feb. 28 . Agricultural Society of England.
Thursday, Feb. 29 . Agric. Imp. Society of Ireland.

FARMERS' CLUBS.

Feb. 20 { Chepstow. / Fairford. / Hadleigh.
March 1 { Wrexham. / Debenham.
Feb. 29 Richmondshire.
March 8 { Cullumpton. / Cardiff. / Gloster.

In continuing the observations we commenced last week, our object is, as it was then, to ascertain THE CHEAPEST WAY OF KEEPING FARM-HORSES; and we are now inquiring into the amount of labour involved in the use of various implements, merely because it is necessary to ascertain how far this affects the evidence offered by many, as to the sum total of the expense connected with horse-labour. It is necessary to know what portion of this sum may be owing to other points of farm management—to the adoption of particular implements, for instance—before we can determine what the tendency of this evidence is. The remark we made in our last *Gazette*, that the total expense of horse-keep incurred by the Berkshire farmer who uses waggons, might be much greater than that incurred by the Scotch farmer occupying the same number of acres of a similar soil, who uses carts, without there being necessarily greater economy in the stables of the latter, was not intended to justify the former in his practice; it was brought forward merely to show, as we have just said, to what an extent the expenses under this head depend on particulars not immediately connected with it; and we shall find that the form of the plough is one of the most influential of these particulars; that the difference in the power required for the performance of a certain amount of work with the cart and the waggon, is not greater than that in the power required to plough a certain extent of land with the various forms of the implement employed in different districts for the purpose.

We do not intend entering now on the subject of wheel and swing ploughs, either as to the quality of the work done by them, or as to the power required to draw them; it is sufficient for our purpose to show that, let the cause be what it may, there is a great difference in the force required to draw different ploughs, when opening furrows of the same dimensions in the same kind of soil. Mr. Pusey, who first directed attention to this subject, detailed the results of his experiments in the English Agricultural Society's Journal, and from his paper we have compiled the following table:—

POWER REQUIRED TO OPEN A FURROW FIVE INCHES DEEP AND NINE INCHES WIDE.

Name of Plough.	Sandy Loam.	Blue Clay. *	Loamy Sand.	Strong Loam.	Moory Soil.	Average.
	st.	st.	st.	st.	st.	st.
Ferguson's Improved Scotch Swing Plough	19	50	19	35	23	29
Clark's Improved Scotch Swing Plough	20	52	17	33	23	29
Kerr's Improved Berkshire, one-wheel	14	43	12	23	16	21½
Ransome's F.P. two-wheels	14	44	12	33	14	23½
Do. do. Swing	18	44	16	30	21	26
King's Swing	18	48	15	27	19	25
Do. one-wheel	17	43	17	30	18	25
Rutland, Ransome's, N.L., two-wheels	17	50	16	36	21	28
Old Berkshire Wheel Plough	20	52	21	36	25	31½
Hillman Plough, two wheels	18					

* The furrow in this case was six inches deep on one side, but the furrow-slice was thrown downwards.

Here we see a great difference in the power required to draw these ploughs—such a difference, in fact, as would force the farmer who employed the one of greatest draught, to keep three horses for every two that were kept by the farmer who used that of least draught.

Mr. Pusey's experiments drew much attention to this subject, and many trials of ploughs have been made since those which he has recorded; the following results of some, which were superintended by the Ipswich and other farmers' clubs, are extracted from the "Farmers' Magazine."

Swing plough—the furrow 9 inches wide by 7 inches deep, down the field, and 9 inches wide by 6 inches deep, up.

Name of Plough.	Maker.	Draught down.	Draught up.
Swing plough, S. R. .	Ransome	20 stone	22 stone
Do. do. F. F. .	Do.	24 ,,	
Do. do. F. S. .	Do.	25 ,,	25 ,,
Palmer's patent W. H. .	Wood	28 ,,	26 ,,
Wooden plough . . .	Meadows	32 ,,	
Essex swing	Ransome	38 ,,	32 ,,

Here the difference in the power required to work the several ploughs is still greater than in the former instance. There cannot be a doubt that many farmers are, from this cause, unwillingly incurring greatly more expense in the cultivation of their land than others, who are careful to select easily-worked implements. The expense of cultivation in many districts is now, also, much diminished by the employment of scarifiers and cultivators in place of the plough; for the extent of land which can be *cultivated* in the course of the day is four times as much as can be *ploughed* in the same time by the same force.

Now, take all this into consideration, and compare two farmers: take the case of one who *carts* his manure to the field, and his produce from it—who, in preparing for Wheat or Barley, the land off which he has just harvested his Potatoes, Swedes, Turnips, &c., instead of ploughing it at the rate of one, or perhaps only ¾ of an acre a day, merely stirs the land with a scarifier or cultivator, which, with the same force, can be done at the rate of four or five acres a day—who, when he does plough, as in preparing the land for fallow crops, &c., uses an implement of the best sort, one combining lightness of draught with efficiency as a plough; and compare this case with that of another who carries his manure out and his crops home in waggons—who uses no cultivator, and ploughs his land with one of the heavy implements named in the above Table. Why, if the latter cultivates his land as well as the former, he requires nearly double the horse-power to enable him to do so; and no straining of economy in the stable will enable him to keep this greater number of horses at the same expense. Indeed, the former may be as economical in the stable as his neighbour, and then what a difference will their respective modes of management make in the accounts which they will render of the expense per acre at which they cultivate their land! Certainly, we shall have closely to examine the evidence on record, of the sum per acre to which the expense of horse-keep amounts on a farm, before, from a comparison of it with the modes of stable-management adopted by the several witnesses, we can determine what true economy in the matter is.

And here we must be allowed a digression, in order to point out the great national importance of this subject. The expense of horse-labour, putting its results out of sight, is a dead loss to the country,—as much so as if its money value were exported; and, in fact, taking its results into consideration, they are obtained in a manner as injurious to the interests of the British labourer, as if the work had been done by a sufficient number of the labourers of any other nation imported for the purpose. We are not, however, here advocating the performance of all Agricultural operations by the hand; it is the interest of the farmer to get his work done in the cheapest manner, whatever be the agent he employs; and as long as the land may be cultivated and crop harvested cheaper by horse-labour than in any other manner, so long will it be unwise to adopt any other plan; but the very statement we have made, when we consider the vast expense thus incurred by the farming interest, shows of how great importance any means are by which its amount may be diminished. We extract the following from a published Lecture, delivered by Mr. Hyett, of Painswick, before the Gloucester Farmers' Club:—

"Some of the very latest improvements, effected by the application of scientific principles, have been mathematically * proved to be the saving in tractive power of one horse in three as applied to the plough; and presuming, as seems more than probable, that equal economy is effected by the use of light carts instead of waggons, and the new cultivators instead of the old scufflers and drags, let us calculate what that saving is. It has been computed in districts where improved implements are used, that two horses are required for every 50 acres of arable land. If the inferior implements were employed, three would be necessary. Take the average value of a cart-horse at 15*l.*, and his annual keep at 36*l.* 10*s.*, or 2*s.* a day. Sir J. Sinclair, in his 'Scottish Husbandry,' gives the annual keep for each horse, averaged for eleven districts in Scotland, as only 28*l.*, or 1*s.* 6½*d.* a day, but the cost of shoeing and gearing, &c. does not seem to be included. Mr. Curtis Hayward, in the Paper which he read to this Club, calculated it, including all these extra expenses, to be with us 2*s.* 6*d.* a day; so I cannot be far wrong in taking the mean, or 2*s.* a day. Suppose a farmer, with 100 acres of arable land on his farm, with unimproved implements, using six—with improved, only four horses; the saving in the first cost of the two extra horses would be 30*l.*, that in their annual keep, 73*l.*, or 14*s.* 7*d.* per acre—a sum, perhaps, nearly equal to half of the average rent of arable land in England.

"To understand how vast the benefit which the country in general might derive from the universal use of these improved implements, let us extend the same calculation to the whole arable land of the country, which I believe I am under the mark in setting at 12,250,000 acres for England and Wales, which at

Three horses for every 50 acres, give	.	735,000 horses
At two ditto ditto	only	490,000 ,,
The number of horses saved being	. .	245,000
Their cost at 15*l.* apiece would be	.	3,675,000*l.*
And their annual keep	. . .	2,942,500*l.*"

* The dynamometer, as affording the measure of the draft of horses, is itself no small debt to science; and perfected as it now is at the Uley Works, by the ingenious adaptation of self-registering machinery, it promises to the farmer information as accurate as it must be valuable.

EXPERIMENTS WITH NITRATE OF SODA, &c.

[We have received the following valuable paper from Mr. Grey, of Dilston. It was written by him in 1841, and being read at the meeting of the Highland Society at Berwick, was printed in the newspaper reports of the time.]

On the 28th April, 1840, I sowed upon each alternate ridge of a plot of land consisting of four acres, of good gravelly loam, which had lain three years in grass and was thickly covered with plants, nitrate of soda at the rate of 1 cwt. per acre, having ascertained the exact contents of each ridge and divided the nitrate accurately into the right proportions. To some of the alternate ridges I applied gypsum at the rate of 10 bushels per acre. To one ridge I applied both the nitrate and gypsum, upon the principle of "the more good things the better;" but the result, in this case, proved the maxim fallacious. And three ridges were left without any application whatever. The Grass to which the nitrate was applied assumed in a few days a darker colour than the other, rose quickly above it in height, came earlier into seed, and was sooner fit for cutting. The plot was all mowed and made into Hay at the same time, great attention being paid to keep the produce of each of the ridges intended for the experiment distinct. The following is the weight of Hay produced by each plot, and at this time the aftermath of those ridges to which the nitrate was applied is obviously better than the others:—

Nature of Manure Applied.	Produce per Acre, calculated from that of 112 square yards.
No manure	2 tons 81 stones
10 bushels of gypsum per acre . .	2 ,, 91 ,,
1 cwt. of nitrate of soda . . .	3 ,, 146 ,,
10 bsh. of gypsum and 1 cwt. nit. of soda	3 ,, 125 ,,

The cost of the nitrate on the ground was 22*s.* per cwt., and the increased value of Hay per acre, as it stood in the fields, would be from 4*l.* to 5*l.*

From the many experiments which have been made, and which have all proved more or less beneficial, no doubt can be entertained that nitrate of soda is generally efficacious in the production of Grass; but several experiments may yet be necessary to ascertain on which description of soil and to what class of plants it is most so, and at what particular stage of their growth it is to be applied with the greatest benefit. I am inclined to think, from the little experience I have had in the matter, as well as from the consideration that it does not act through the medium of the soil, as a manure, but rather as a stimulus to the plants, that it ought not to be sown upon the Grass until it has risen considerably from the ground and the blades are sufficiently evolved to derive all possible benefit.

I applied nitrate of soda to a row of Potatoes, at an early period of their growth. The tops soon showed the effect, and far outstripped the adjoining rows in growth; but when the Potatoes were taken up the produce of that row was found to be less than that of the others, both in weight and measure.

The first action of the Potato plant is to throw out its top. The roots make their growth at a later period. It seems in this instance that the stimulus of the nitrate had expended itself in the earlier process, and that the roots, instead of being benefited, had suffered by the application—probably from the greater shade and weight of top.

I applied nitrate and gypsum also to alternate ridges of different kinds of grain and at various stages of its growth, but the quantity of rain that fell in this part of the country, both previous to and during the time of harvest, had the effect of producing so much straw, and of laying the corn so flat, that it was found difficult to cut the plots so as to keep the produce of each perfectly distinct, and was also in other respects so unfavourable to the experiment that I cannot reckon upon the result being very correct and satisfactory. In one case where the Barley was very bulky, and in consequence much lodged, the grass seeds were found to be weak and worse than in any other part of the field; but in another instance the reverse of this was the case. The crop was a thin one of winter

Wheat, on poor clay land. Four ridges were sown with nitrate when the Wheat was about a foot high; little effect was perceptible during its growth, save in a darker shade which it assumed, as is common to all crops where nitrate is applied; and on being cut those ridges produced no few sheaves more than the others, that I was not induced to keep their produce separate; but in the spring of the following year, the new grasses upon them were found to be much better than upon any others in the field. The pasture was heavily stocked with ewes and lambs, and eaten bare, the sheep giving those ridges the preference. When the lambs were weaned, the pasture was cleared of stock for a fortnight, when the same thing was repeated; the grass on those ridges again took considerably the lead of all the rest, and was again preferred by the sheep when they returned to it. This was a result which I had not anticipated, and proves either that the effect of the nitrate continued in operation during the following season, or that its effect in the first year upon the grass was such as to nourish and strengthen the plants so much as to cause them to stand better through the winter, and to shoot out much more vigorously in the spring. The latter is, I think, the more reasonable conjecture.

In the beginning of May last, (1841,) I applied nitrate of soda and a mixture of nitrate and manganese to equal quantities of grass of the first year's seeds, intended for mowing, leaving a portion without any dressing. The land was well covered with plants of red and white Clover and Rye Grass, but not of first-rate quality. Both portions to which the dressings were applied soon assumed a dark appearance and a rapid growth; the difference was perceptible at any distance from which the field was visible. The different portions were cut, and the produce of each carefully kept distinct and weighed when made into hay and put up in pikes, of which the following is the result:—

Description of dressing.	No. 1. Nitrate of soda, 1 cwt.	No. 2. Manganese and nitrat. of soda, equal quantities, 1½ cwt.	No. 3. No dressing.
Weight of Hay per acre.	3 tons 88 st.	3 tons 21 st.	2 tons 37 st.
Value of Hay on each acre, at 3l. per ton	£ s. d. 10 18 0	£ s. d. 9 7 10½	£ s. d. 6 13 10½
Cost of each top-dressing per acre	1 6 0	1 1 0	0 0 0
Value of Hay per acre, deducting expense of top-dressings	9 7 0	8 6 10½	6 13 10½

When the aftermath had begun to shoot up, I applied the same dressing as above, and also a mixture of guano and soil to portions of the land which were left without anything before. The effect as to colour and growth was the same as in the previous experiment, from the nitrate and manganese. That from the guano was less apparent and slower, but still the growth was greater than where nothing was applied to the grass. One thing was very obvious, that the stock when put into the field gave a great preference to the portions which had received the saline dressings over that to which guano had been applied, as well as to that which had nothing.—*John Grey, Dilton House.*

(To be continued.)

REPORT OF DR. VON MARTIUS ON GUANO.

In answer to the summons of the general committee, I have the honour to submit the following report upon the nature of guano, upon its history, and also its utility as a manure in Bavaria. Guano is the excrement of various sea-birds, as the cormorants, flamingoes, cranes, &c., and is found on many little islands off the coast of Peru, situated between 13° and 21° south latitude. Its quantity is so great that it is obtained by means of mining operations. The word guano belongs to the old Peruvian or Quichua language, and signifies muck, or dung. It is pronounced Huana by the Peruvians, which the Spaniards, according to the genius of their language, spell guano. This substance was known to the inhabitants of Peru as a valuable manure long before the possession of their country by the Spaniards; and the success of the culture of the barren sandy tracts of land along the coast depended in a great measure on the use of this substance, so favourable to vegetation.

The use of guano as a manure was first mentioned by Inca Garcilasso de la Vega, a Spaniard who wrote on Peru as early as 1723, in a work entitled "Commentarios Reales." "On the sea-coast," says he, "between Arequipa and Tarapaca, in a tract of land more than two leagues in length, they have no other kind of manure than that afforded by sea-birds, which dwell in countless numbers on the sea-coast. They lay their eggs on certain islands along the coast, and the quantity of excrement they leave there is astonishingly great. At a distance *the masses of excrement look like the tops of a range of hills.* At the time the Incas governed Peru the birds were preserved with great care. The punishment of death was decreed against those who landed on the island during breeding-time, or frightened the birds, or at any time destroyed them. Each island was a distinct province, or, when large, was divided into several provinces, over each of which an overseer was appointed by the Incas, whose care it was to see that every district had its due proportion, and no one defrauded his neighbour of the universally-needed manure."

Frezier, who travelled in Peru in 1712 to 1714, mentions having seen in the port of Arica, and in the island of Iquique, the guano dug up by Negroes. About the same time Feuillé also speaks of the pestilential exhalations from the guano islands, and of the ships (*Guaneros*) employed along the coast for its exportation. Ulloa, also, later reported on it in his great work upon Peru. Alexander von Humboldt was the first who brought specimens of guano to Europe, which was in 1804. He sent specimens for examination to Vauquelin, Fourcroy, and Klaproth*, and spoke of it himself in the following manner:—"The guano is deposited in layers 50 or 60 feet thick on the granite of many of the South-sea Islands, off the coast of Peru. During 300 years the coast-birds have only deposited guano a few lines in thickness. This shews how great must have been the number of birds, and how many centuries must have passed over in order to form the present guano-beds."

Humboldt put the question to Klaproth as to whether the guano had been deposited on the present islands, or had been thrown up by some convulsion of nature. Although at first sight the simplest explanation appears to be that it was deposited by birds in its present position, yet an objection occurs from the fact that neighbouring islands present no guano. But this objection may be overruled by the well-known fact that birds return always to the same places to nidify, and an analogous phenomenon takes place in those islands which are exclusively sought by turtles for the purpose of laying their eggs. But be this as it will, the guano exists in such quantities as to give it the importance of a geological formation, and in this respect is the counterpart of those formations which owe their existence to animals, as those formed by species of recent infusoria.

The guano layers, according to the length of time they have been deposited, have undergone many changes. Here and there they are covered with siliceous sand, and have thus been protected from the influence of the weather. In other places, on the other hand, they are open and exposed to the action of light, air, and water, which have effected in them many decompositions. Such changes are indicated in most cases by an ochre-yellow guano, resembling Spanish snuff, the colour changing according to the greater or lesser amount of decomposition. Fresh guano is of a white colour, but that which is dug up has a bright or ochre-yellow, brown, or red colour. The chemical composition of guano is very various; and this point should be attended to where large quantities are bought, as some sorts are worth nothing like so much as others.

(To be continued.)

* For the results of the examination of these chemists see "Memoires de l'Institut," tom. vi.; and Klaproth's "Beitrage," vol. vi.

ON MINERAL AND INORGANIC MANURES.

No. VII.

By Professor Charles Sprengel.

2. *Chalk.*—Chalk is one of the most recent lime formations; and although it consists chiefly of carbonate of lime (lime and acid combined in the same proportion as in the limestones), it contains always more extraneous admixtures than the solid limestone,—so much so, that it often passes into marl. To these admixtures—clay, silica, magnesia, phosphate of lime, common salt, &c.,—its value as a manuring substance is chiefly owing. If it contains much clay, like marl, it will fall to pieces if lying in the open air, as the marl does; if it contains much silica it must be burnt first like the lime, else it will not fall to pieces; but in burning it, too much heat is to be avoided, else a silicate of lime will be produced. At times chalk is so earthy, that it can be easily broken in pieces, and then it may be used without being burnt. In this case, however, it will never manure so well as if it had been burnt, as it will be deficient in caustic properties, and must then be used in large quantities, in order to produce any striking result. If earthy chalk be burnt, large lumps of it are first baked, and then placed in kilns constructed for that purpose. Whenever fuel is not too expensive, it will always be best to use chalk in a burnt state, especially if a ferruginous, sour, clayey, or peaty soil is to be acted upon. It is true, a clayey soil may be also improved mechanically by unburnt chalk, but then it must not be too stony, and large quantities must be used.

If chalk is burnt, its effects are similar to that of lime; if unburnt, it acts like marl, of which we shall speak presently. Of burnt chalk no more is required, per acre, than of burnt lime; of unburnt, however, the quantity is to be as great, or even greater, than of those marls which are richest in lime. It must be taken into account whether chalk is earthy or stony; because, as the latter acts but very gradually, a much greater quantity will be required. In meagre, light soils, however, neither earthy nor stony chalk will act beneficially, which might naturally be expected, as these soils are deficient in most substances which plants require for nourishment, and such chalk does not convey to the ground any of those substances except lime. I once saw earthy chalk used with great confidence on a clayey soil not deficient in humus, but the result was so much less than was expected, that the experiment was never repeated.

3. *Marl*—which has been used from time immemorial as a manure, is a compound of clay and carbonate of lime. Still, however, chemical analysis proves that most sorts of marl contain more or less of carbonate of magnesia, gypsum, common salt, silicate of potash, silicate of soda, manganese, quartz, and some other substances. These must not be left unnoticed, because we shall see presently that it is on these very substances, hitherto not duly taken into account, that the value of marl depends. According to its predominant constituents, it bears the name of lime, magnesia, clay, and sand-marl.

A characteristic criterion of marl is, that being exposed to air it will fall in pieces, which is caused by the various degrees in which its component parts attract water; and as different degrees of expansion are thereby produced, it is obvious, that on becoming successively wet and dry, these parts will separate from each other.

There are earthy and stony marls. The former is mostly found in the diluvial formation, and owes its origin to a most diversified composition of mineral substances (*vide* my treatise on soils). Some distinguish also a shell-marl, which is mostly composed of decomposed *molusca*, and is to be found mostly in low grounds under a marshy soil, consequently where, most probably, fresh-water lakes existed at a former period. Under this name, also, may be considered that calcareous earth which near the sea-coast underlies marshy localities.

It is by the carbonate of lime and magnesia contained in marl that the effervescence is caused which takes place when mineral acids are poured on it, as by these, carbonic acid is driven off, and escapes in the form of gas. Its colour, at times green, blue, violet, yellow, red, or brown, is owing to both oxides of iron (protoxide and oxide), and if the colour of marl be grey, black, or blackish-brown, it is owing mostly to an admixture of coal, bitumen, or humus. The value of marl, however, as a manure can never be arrived at, either from its colours or the degree of its effervescence with an acid, or by any other external criterion; this can only be done by chemical analysis, because, at times, it is owing to the presence in it of substances existing in very small quantities, and not discernible by outward appearance. It is with marl as with all other manures, it is useful only when it contains substances in which the soil is deficient. If, for instance, the soil does not contain enough gypsum, but, with this exception, if it contain all other mineral substances in such proportions as are required for the nourishment of plants, for such a soil, we say,—a marl which contains no gypsum has little or no value. If, on the contrary, a marl contains but little gypsum, it will improve a soil which is entirely deficient of that mineral, even if it contained so little carbonate of lime, that it could hardly claim the name of marl at all. It is the general opinion that that marl is best which contains most carbonate of lime; but this is fully contradicted by experience, although it cannot be gainsaid, that this is one of the most effective and powerful of its ingredients. That sort of marl, therefore, which may be very valuable for one sort of soil, is valueless for another; for the chemical constitution of the soil must always be taken into account. It may be generally assumed, that that sort of marl will be best which contains all the substances required for the nourishment of plants in a due proportion, as in this case, even if the soil to be manured should possess some other nutritive substance, it will be improved by the other component parts of the marl. Silica, however, may be excluded from this calculation, as most soils, moors and marshes excepted, contain a sufficient quantity of it. A marl which consists merely of carbonate of lime and clay possesses but four substances which improve vegetation; whilst a marl, which, besides these two component parts, contains also gypsum, common salt, silicate of potash, phosphate of lime, saltpetre, manganese, and magnesia, will yield to the plants twelve different nourishing substances. It is obvious that a marl which contains many nutritive substances of plants must be preferable to one which possesses but few. If, therefore, any marl contains all the mineral substances which the plants require for nourishment, it may be used to advantage on all sorts of soils; but if, on the contrary, it contains only 4, 5, 6, or 7, it will act beneficially only on such soils as are deficient in those ingredients which it contains. An absolutely and a relatively good marl may thus be distinguished, the former being met with but very rarely in nature, the latter most abundantly.

(To be continued.)

ON THE APPLICATION OF CHEMISTRY TO AGRICULTURE UPON RATIONAL PRINCIPLES.—No. VI.

(Continued from page 91.)

I will now proceed to treat separately of the two classes of chemical constituents in all plants—Organic and Inorganic, the elements of which must in some form or other be supplied to the plant.

1.—Of Organic Principles:—

A—Non-Azotized.

Represented by
- *A* Sugar
- *B* Starch
- *C* Gum

} Saccharine group.

- *D* Oil
- *E* Fat
- *F* Wax

} Oleaginous group.

B—Azotized.

Represented by
- *G* Vegetable Fibrine
- *H* —— Albumen
- *I* —— Casein

} Albuminous group.

2.—Inorganic Principles:—

Are principally
- Lime
- Silicon
- Muriate of Soda (Salt)
- Carbonate of Potash or Magnesia
- Phosphorus
- Sulphur
- Iron,

and the ultimate chemical composition of the above will be seen at a glance of the following table. Those who wish for further information will readily find it by reference to Turner, or any other elementary work on Chemistry.

		Organic Principles. Oxygen.	Nitrogen.	Carbon.	Hydrogen.
Non Azotized.	Sugar	51	—	42	7 = 100
	Starch	49	—	43	8 = 100
	Oil, fat, &c.	9½	—	79	11½ = 100
Azotized.	Albumen, Fibrine, Casein	22	16.	55	7 = 100

The difference in chemical composition of the azotized group is so slight, that I have classed them together as identical, which they are, according to the testimony of

Liebig. Under the head of oxygen, also, in the same group, a slight proportion of sulphur and phosphorus is included. I have taken round numbers to avoid the inconvenience of decimals.

Of the Inorganic Principles; iron, sulphur, phosphorus, and silicon, are elementary. Muriate of soda, or, more properly speaking, chloride of sodium, consists of two elementary principles, chlorine and sodium; and the salts of potash, or magnesia, consist of carbonic acid and the oxides of potassium and magnesium.

With the exception of gelatine, which is produced by the metamorphosis of albumen, the above are also the constituents of all animal structure. The world of vegetable and animal life is, in reality, resolvable into the following elements:—

Oxygen
Hydrogen
Carbon
Nitrogen;

with deposits in cellular structure of one or more salts of the following:—

Calcium or Magnesium
Sodium or Potassium
Phosphorus
Iron
Silicon

These elements, moulded into being by the hand of Creative Wisdom, and endowed with the mysterious and incomprehensible principle of life, become converted into the endless races of animals—immense forests—the deep water of the sea, or the atmosphere that supports and retains the vitality of living beings.

Now, I do not consider that much knowledge will be gained by the Agricultural student of chemistry, by confusing himself with minute descriptions or details of particular analysis; instead, therefore, of a great array of figures, which nobody can understand but chemists themselves, I shall content myself by making some simple observations separately upon each of the constituents of plants.

Of the Saccharine Groups: Sugar, Starch, Gum.—There are two varieties of sugar, one derived from the cane, called CANE SUGAR; the other produced by the transposition of the elements of starch in ripening fruits, called GRAPE SUGAR. It is the latter of these, as an element of food and a constituent of plants, which I shall consider here.

If you cut an unripe Apple or raw Potato, and rub the cut surface upon a grater, a solution of very fine flour of pure starch will be obtained. In the unripe Grape, in Turnips, Mangold Wurtzel, the grain of Wheat, Barley, or Oats, Beans, Peas, &c., it is very abundant. In the process of ripening fruit, which we well know requires heat, this starch is converted into sugar by a simple transposition of elements, which a reference to the composition of the substances will show (*vide* table). This change also takes place in the process of malting, the success of which operation depends upon the existence of the principle of life in the seed. Now this vital principle, of the nature of which we know nothing, and very probably never shall, is, from the commencement to the end of life, constantly effecting the most profound chemical changes in the living body. In the instance before us, chemical action is induced to convert the starch into food for the embryo plant. During the change, a reference to the table will show that carbonic acid is constantly set free. Now this carbonic acid nourishes the embryo plant, precisely in the same way as the carbonic acid, which results from the decomposition of humus, nourishes it in a future state of its existence. But the maltster wants all the sugar he can get in his malt. When, therefore, the experienced maltster finds by the length of the germ or root that the ever-acting chemist, life, has changed the whole of the starch in the seed into sugar, he destroys the life of the embryo by heat. If he did not do this at the proper time, his malt would be spoiled, for the growing plant requires food, and quickly appropriates the sugar to its own use. As an instance of the transposition of chemical elements, let us pursue this digression a little further; when the malt comes into the hands of the brewer, his object is to obtain an *alcoholic* solution, called beer. He first dissolves all the sugar in the malt by boiling, after which his object is simply to convert the sugar into alcohol; in equivalents the following is the composition of alcohol and Grape sugar:—

	Carbon.	Hydrogen.	Oxygen.
Alcohol	4	6	2
Sugar	12	14	14

By chemical calculations, which would be out of place here, it can be proved that the results of the change in the sugar is alcohol, carbonic acid, and water; the carbonic acid being given off during the change or fermentation, and the water serving as a solvent for the alcohol.

Now this fermentation is produced by the action of life. Yeast is a plant of a low organisation, and is constituted of a number of small spherical cells united together in a line. Each of these cells contains many germs, which, by the constantly-repeated deaths and bursting of the parent cells, become free, and form full-grown cells themselves. In this manner the yeast-plant rapidly grows throughout the cask of sweet-wort, and produces the change of sugar into alcohol, with the constant escape of carbonic acid from the surface, which is called "the working of the beer." The importance, then, of sugar existing in plants, either as a distinct compound, or by its elements in the form of starch, will be apparent.

Starch, or principles similar to it, exists in all plants connected with Agriculture. It is an essential ingredient in the food of animals, because it is absolutely necessary to support the functions of respiration and animal heat. It is a valuable principle to the farmer, for it is necessary in fact to produce fat; and it is equally essential to the reproduction of the crop, for without it seed would not germinate.

Gum is found in the bark and wood of all plants. It is well known in its simple form as gum arabic, and it is highly nutritious both to man and animals. Six ounces of gum arabic have been found sufficient to support an adult man or woman for twenty-four hours. This, however, could not continue long, as the want of azotised food would prove fatal to the experimenter. The same remark applies to sugar and starch; they are highly nutritious as supporters of respiration, but alone are incapable of supporting animal life. Woody fibre, which is very nearly the same in chemical composition in all plants; in the Turnip-top, or the ship's mast; is represented by the Saccharine group *. It is, in fact, very easily converted into sugar; 100 parts of linen rags will yield 114 of sugar, when treated with sulphuric acid.

As I have not attempted a chemical dissertation upon the different parts of the plant, I have said nothing about the sap. I may observe, however, that the ascending sap is nearly similar in all plants, but that important changes take place during its circulation in the leaves. Much interesting and valuable information on this point, written with peculiar clearness, may be found in Professor Henslow's Letters to the Farmers of Suffolk, or Dr. Carpenter's Popular Cyclopædia, vol. Vegetable Physiology and Botany—a very excellent and cheap publication.—*C. R. Bree, Stowmarket.*

(To be continued.)

Home Correspondence.

Superphosphate of Lime.—The following is the best process for forming superphosphate of lime and other salts of phosphoric acid. I give the process that I used before I possessed appropriate machinery for mixing the acid with the bones. By means of this machinery I am capable of greatly reducing the quantity of water which is otherwise necessary to effect the complete decomposition of the phosphate of lime. Calcined bones are to be reduced by grinding to a very fine powder, and placed in an iron pan with an equal weight of water (a cast-iron trough, such as are sold for holding water for cattle will do); a man with a spade must mix the bone with the water until every portion is wet: while the man is stirring an assistant empties at once into the pan sulphuric acid, 60 parts by weight to every 100 parts of bone; the acid is poured in at once, and not in a thin stream, as commonly recommended; the stirring is continued for about three minutes and the material is then thrown out. With four common farm-labourers and two pans, I have mixed two tons in one day, the larger the heap that is made the more perfect the decomposition, as the heap remains intensely hot for a long time. It is necessary to spread the superphosphate out to the air for a few days, that it may become dry. The great mechanical difficulty of reducing unburnt bones to a very fine powder renders the formation of superphosphate of lime from them very difficult, but common bone-dust in a pure state (that which is sold contains about one-third of lime) may be decomposed by boiling it in a leaden pan with half its weight of sulphuric acid and twice its weight of water, which may afterwards be dried up with sawdust or clay-ashes.—*J. B. Lawes.*

In what do the Fertilising Qualities of Bones consist?—There seems still to be some doubt in the minds of some of your readers whether the phospate of lime, or the gelatine, is the fertilising substance in the bone? I would suggest the following experiment, which I have tried myself, and which has satisfied me that the animal matter in the bone merely acts by yielding, by slow decomposition, phosphate of lime in a state capable of being assimilated by plants; and to the phosphate of lime bring in a similar state in guano, and not to the ammonia contained in it, may be attributed the powerful effects of this valuable manure. To every 100 parts of large bones add 400 parts of water and 100 parts of muriatic acid, let it stand for four or five days, and then drain off the liquid, and add the same quantity of fresh water and acid four times; by this means the whole of the phosphate of lime will be dissolved in the liquid, and the bones will retain their original form; they must be repeatedly washed until the water ceases to taste acid, then dry them in an oven, and rub them to powder. Evaporate the whole of the liquid in which the mineral matter of the bone was dissolved until nothing but a dry paste remains; heat this to redness, rub it to a fine powder, and convert it into superphosphate of lime in the manner already described. Let two equal quantities of ground be sown with Turnips, strain the seed and one of these two manures together, and the result will satisfy the most sceptical. I have lately seen a large quantity of Swedes growing upon the light sands of Norfolk, in which four bushels of my superphosphate of lime per acre were used, and the crops were excellent,—the superphosphate was formed from calcined bones which did not contain one-half per cent. of carbon.—*J. B. Lawes.*

A Word in Favour of the Rooks.—Having observed in the 4th Number of the *Agricultural Gazette* that a meeting had been held in the town of Dumfries, Scotland, for the partial destruction of the rooks in that district, we beg leave to offer a few remarks in their favour. These birds certainly eat grain and Potatoes, but it is much to be questioned whether, when following the sower in the field, they are not more intent upon the larvæ of numerous insects, which the operation of ploughing and harrowing brings to the surface, than upon the grain which is scattered amongst them. The crops of these birds, at the period under consideration, will be found to be more abundantly stored with worms and various insects, both in their larva and perfect state, than with grain; and what they do eat would not be the tenth of what would be consumed by the insects which they destroy. We find the following in behalf of the rooks in the "American Farmer." "Every crow requires at least one pound of food a week, and nine tenths of their food consists of worms and insects; 100 crows, then, in one season, destroy 4,780 lbs. of worms and insects." From this fact some idea may be formed of the benefit of this much persecuted bird. Were it not for these useful birds our fields would soon swarm with the larvæ of insects, which would, if left to have their own way, let neither man, bird, or beast reap the fruits of the earth. If we look to those countries where these useful birds are persecuted, we shall find that the formidable cockchafer (Melolontha vulgaris) and other destructive insects, destroy nearly the whole of our field and orchard crops; while in those places where these useful birds are allowed to remain unmolested, the ravages of these destructive insects are unknown. Natural instinct seems to direct the rook to this species of food, while man is unconscious of the circumstance. Thus we often see flocks of these birds busily employed in grass-land and meadows, picking up food which is not visible on the surface. From observation we can assert that their employment in such cases is in perforating the surface-sward with their bills to search for the larvæ of different insects, which are, at the same time, actively devouring the roots of the grass. Even while engaged in this important service, the husbandman in nine cases out of ten drives them away. In this district the rooks migrate as soon as the operation of sowing is finished, taking with them their young, spending the most of the summer on large heaths and moors but scantily supplied with food. They again return to us towards autumn to destroy the perfect insects, many of which begin at this time to deposit their eggs. At this period rooks do infinite good, as for each insect they destroy they are the means of destroying many. It has been observed that the sole employment of the rooks for three months in spring is to search for this kind of food, and the havoc a numerous flock makes amongst these destructive insects must be very great.—*J. Mc I., Hillsborough.*

Preservation of Root Crops.—The usual method of storing Swedes, either by earthing up in the field or covering in pits, is liable to objections. Having preserved Carrots by cutting off the upper part as well as the green top, and letting them remain earthed up in the ground where they grew, I have this season been induced to try the same method upon a small patch of Swedes. If covered in the field they sprout, and otherwise lose much of their nutritive properties; if put into pits the fermentation which takes place is still more injurious in this way. By letting them remain in the ground, preventing germination and covering the top with mould, I believe we shall best succeed in preserving their enriching properties uninjured. The process of cutting off the top may be done with a hoe, but it requires a deep cut beyond the germinating circle, and all that is cut off should be taken to the sheep-fold, so as not to waste a leaf. The earthing up is a very easy process—supposing the Turnips drilled, as the double mould board plough drawn between the rows is sufficient.—*S. C.*

Another New Manure.—I send you a specimen of the dung of Bats, received from Jamaica. It is found in considerable quantity in the Caves near Dry Harbour, and in the Guy's Hill District, in the parish of St. Ann, in that island. The following analysis is by F. J. Fleming, Esq., a Member of the St. Ann's Agricultural Society:—

500 *Grains of the Matter appear to be composed of*

Water of Absorption	116
Uncombined Phosphoric Acid	4
Oxide of Iron	3
Phosphate of Lime	181
Carbonate of Lime	16
Animal and Vegetable Matter, giving out a fœtid gas by combustion	99
Matter indestructible by Heat	81
Grains	500

This substance, which is of a dark or chocolate colour, is expected to prove a highly valuable manure; it had been tried by covering it with earth in the cane-hole; but a writer in the *Jamaica Times* suggests that it should be used broadcast, being previously mixed with wood-ashes or powdered charcoal.—*T. E.*

Bones.—The supply of Bones for crushing is not now so plentiful as formerly. There are large quantities of the bones of the small Whales, which are killed in hundreds at a time, lying on the sea-beaches of Orkney, Shetland, and the Faroe islands, and which probably may be had for the trouble of collecting. It may be well for those concerned in crushing bones for manure to look to these quarters; and also to induce Whale fishers, who go to the Greenland seas, to save as great an amount of the skeletons as possible, to be brought home; or to have them towed on shore, to be sent for afterwards. The Seal fishery might also supply a very large store.—*G.*

Steeping Seeds.—It may not be uninteresting to know that the practice of steeping seeds, recently brought under the notice of the Highland Society by Mr. Campbell, of Dundee, was tried 150 years ago, as appears from the subjoined extract from the "Farmers' Magazine" for December, 1810. The experiment there mentioned seems to have been even more successful than those of Mr. Campbell. To him, however, the farmer's thanks are due for reopening the subject, at a time when the attention of eminent scientific men is so much directed to making their discoveries available for the purposes of Agriculture:—"Charles Miller, son of the celebrated botanist, published

* Starch, sugar of milk, woody fibre, cane-sugar, and grape-sugar, all contain the same quantity of carbon, united with different quantities of oxygen and hydrogen, in the proportions to form water.—*Turner's Elements*, p. 921.

a recipe for fertilising seed, and tried it on Wheat, by mixing lime, nitre, and pigeon's dung in water, and therein steeping the seed. The produce of some of these grains is stated at 60, 70, and 80 stems; many of the ears six inches long had 60 corns each, and none less than 40. This experiment was made in 1692 (see "Everard's Essays and Experiments"); yet I do not find the idea acted upon. I incline to think it founded on nature, and worthy of serious investigation. We are careful to fertilise the soil—why not the seed?"—*James Caird, Balloon, Wigtown.*

Cheap Method of Bruising small Quantities of Bones.—In your third Number, under "Notices to Correspondents," I observe "*Waste of Bones*—There is no cheap machine that we know of for crushing bones," &c. This induces me to send you the following cheap method which I tried last year with good effect:—Strew them on a hard road with a quantity of burnt soil near your fold-yard, where you are going to cart out manure or soil, so that the wheels may pass over them. Rake them occasionally to those tracks over which the wheels run; the burnt soil will absorb the oily matter expressed. Gather them up at night and pass them through a riddle, and what will not go through put down again the next day on the road with more burnt soil. It should be a fine day.—*F. M.*

Loss of Crop by Exposure of the Manure to the Action of the Weather.—On the 28th of April, 1843, in planting Potatoes we spread the manure for 19 ridges, but we could only complete 12 before night came on, and the following morning being rainy we could not proceed; the 30th was Sunday (a sunny day), and on Monday morning we finished the remaining seven rows. The 12 rows first planted came up a week before the others, and distinctly kept the lead throughout their growth, so much so, indeed, that if we had not noted the circumstance at the time, we should have been at a loss to account for the great difference between the two plots, both manure and sets being alike for each. On the 27th October we raised the crop, and the seven exposed rows yielded less in weight by 5st. 3lbs. per row than the other 12 rows—the length of the rows was 75 yards, thus showing a lighter crop by 3¼ tons to the acre; the Potatoes too were scabbed and inferior in quality. The manure was night-soil and ashes, with Epsom salts. My attention was drawn to the effect of the weather upon exposed manure by a former article in the *Chronicle*, and there certainly is not a more important matter connected with improvement in farming than the economical treatment of manure.—*A Subscriber.*

Draining Materials.—Living in a part of the country where tiles are dear, and having plantations of Scotch Fir to thin, I thought of trying some of the thinnings as a substitute. I took some of the worst growers, from 12 to 20 feet long, and averaging 4 to 5 inches diameter, and I cut them lengthwise with the saw, and laid them at the bottom of the drain, turning the convex sides inwards, which then touched each other along the centre. The flat sides were then placed close against the banks, and being covered with Heath the drains were filled up in the ordinary way. Semicircular stuff thus placed of course leaves a hollow space both above and below; and while the under one here answers to the tile-tube, the upper far surpasses in efficiency the few small holes pierced in the tile for the percolation of the top water into it, the flat sides pressed against the bank giving it a tendency to run to the centre, and at the same time preventing the soil from falling in upon it. This plan was tried on a flat meadow, so wet as not to admit of a man's weight without 'podging,' as it is called. In less than a month after drainage this meadow would bear cattle upon it, and young Clover began to spring all over the field. This success makes me doubt whether this is not a more efficient mode of draining than that with tiles, carrying off the water quicker, and not being so liable to break in its course by the pressure of weights passing over the drains; and the wood, I apprehend, so excluded from air, will last a number of years, especially if cut when the sap is in it.—*A Surrey Farmer.*

Nitrate of Soda.—In November, 1842, a field of six acres was sown with Wheat. Soil, a strong clay; the previous crop, Beans. I think it was owing to the abundance of rain in the spring of 1843, that the plant assumed a sickly appearance. Wishing, if possible, to recover it, I applied, in May, as a top-dressing, 2 cwt. of nitrate of soda per acre, to half the field. To the other half I applied guano, allowing the same quantity per acre. In a few days the Wheat on the land on which the nitrate of soda was sown was visibly altered, and soon had quite a healthy and rank appearance. That to which the guano was applied did not improve at all, and at the time it was harvested had its original unhealthy and stunted appearance. The straw of the plant to which the nitrate was applied stood on an average seven inches higher than that in the other part of the field, the grains were likewise considerably larger, and the ears better filled. This fact I mention to show that as a top-dressing for Wheat, I did not find guano answer; but when hoed, harrowed, or drilled in, I understand from those who have tried the experiment, its effects are highly beneficial.—*Yeoman.*

Liming Land with a Northern Aspect.—In the translation from Professor Sprengel's account of lime, published in your Paper of the 27th ult., is the following observation:—"It is asserted that the manuring with lime is injurious on fields that slope much towards the north," &c. It is evident to those who have been in the habit of liming for Wheat, that the plant does not look so thriving in the winter as on unlimed ground, but from the end of March, or at least when the weather begins to improve, and the sun gains more power, the crop manured with lime gradually takes the lead, and keeps it till harvest. Lime certainly is a good conductor of heat, as is proved by the rapidity with which a heap of mortar freezes when exposed to a low temperature. This may in some measure account for lime not being so beneficial on land much exposed to the north, because such a situation is not only much exposed, but it is also nearly deprived of the rays of the sun in the short days during the winter months. I am convinced of the benefit of lime as a manure for Wheat, and should not hesitate to use it in moderate quantities with a northern aspect, but in that case I should recommend the lime to be laid on early in the summer, before the first ploughing. By this means all the advantage of the manure would be obtained and the injurious effects avoided.—*A. Hall, Chepstow.*

Means of improving the Quality of Manure.—My experience and observation have taught me that great care should be taken of the liquid manure, and that well-constructed tanks should be formed conveniently to receive it as it flows from the cow-houses, from which it should be pumped and carried back to the yard to saturate the dung-hill, this being of great advantage in assisting decomposition. The midden-stance would require a very small inclination towards the tanks, so that the surplus sap, after saturation, may return. The urine requires to be diluted with an equal quantity of water, to enable it to retain its ammonia. Each addition to the manure-heap should be regularly spread, with a small quantity of sulphuric acid or gypsum strewed over the surface to prevent the escape of ammonia. A large quantity of straw may, by this process, be converted into excellent manure, when mixed with the dung from the cow-houses and stables; but I quite disapprove of the frequent turnings in many places given to manure, which causes it to lose much of its fertilising property. I would advise "R. C." to sow a little of the approved mineral manures along with his crops, rather than mix them in his muck. Now that there is a spirit of inquiry amongst our Agricultural population, I hope a judicious plan will soon be adopted of collecting and manufacturing the cloacine and manures of our large towns, to admit of their being transported to a distance. In many towns the common sewers run into rivers, the matter they contain being thus entirely lost. But if the authorities would take up the subject, a plan might be devised to retain the sediment, and have it formed into a transportable manure. It would become an important branch of industry, and save many thousands to the United Kingdom now paid for foreign manures—*A Perthshire Farmer.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

At a weekly council, held at the Society's House, in Hanover-square, on Wednesday last, the 14th of Feb.: present—his Grace the Duke of Richmond, K.G., in the chair; Earl of March, Thomas Raymond Barker, Esq., F. Burke, Esq., F. C. Cherry, Esq., A. E. Fuller, Esq., M.P.; H. Gibbs, Esq., B. Gibbs, Esq., L. Rogers, Esq., Professor Sewell, H. S. Thompson, Esq., and George Wilbraham, Esq., William Holbeck, Esq., of Farnborough, near Banbury, Oxfordshire, and Henry Hoghton, Esq., of Bold, near Warrington, Lancashire, were elected Governors, and the following gentlemen Members of the Society:—

Whittam, James Sibley, Mayor of Coventry
Mundy, Chas. John Henry, Mavis-Enderby, near Spilsby, Linc.
Randall, Robert, Flamstead House, Redbourne, Herts
Lysons, the Rev. Samuel, Hempsted-court, near Gloucester
Child, Thomas, Mickelham Priory, Hartshorne, Sussex
Carnegie, the Hon. J. J., Fair Oaks, near Petersfield
King, John, The Grove, Exton, Alton, Hants
Strode, Jas. Cranborne, Brighton
Warde, Charles, Squerries, near Westerham, Kent
Beevor, Henry, Barnby Moor, East Retford, Notts
Rickaby, John, Ulrome House, Bridlington, Yorks.
Eddison, William, Huddersfield, Yorks.
Gibbons, William, Foxgrove-farm, Beckenham, Kent
Dandridge, Daniel, East Hendred, near Abingdon
Alston, Wm. Chas., Elmdon Hall, near Birmingham
Vivian, Edward, Torquay, Devon
Williams, Captain, Torquay, Devon
Elliott, Jonathan, Sonning, near Reading, Berks
Pelly, Richard Wilson, Upton, Essex
Webb, William, Haselor, near Tamworth, Staffs.
Pain, John, Houghton, near Stockbridge, Hants.
Dolphin, John, Hunter House, Edmondsbyres, Durham
Boddam, Joseph, Newton-Stanhope, Weardale, Durham
Grosvenor, The Earl, Grosvenor-square, London
Roach, John, Perreton, Newport, Isle of Wight
Brook, James, Park Farm, Brading, Newport, Isle of Wight
Wavell, William, Lake, Newport, Isle of Wight
Sclater, Wm. Lutley, Hoddington House, Odiham, Hants
Atkinson, Joseph, Grazing-nook, Bedale, Yorkshire
De Berg, M., Secretary to the Russian Embassy in London, 30, Dover-street
Pope, John Allen, Clifton Farm, near Yeovil, Somerset
Johnson, Francis Dixon, Aykley Heads, Durham
Wilkinson, Percival Spearman, Mount Oswald, Durham
Cooper, Wm. W., Barningham Park, Ixworth, Suffolk
Courtney, Thomas, Stratton, Andover-road, Whitchurch, Hants
Bailey, Frederick, Mitcheldever, Andover-rd., Whitchurch, Hants
Shearer, Bettesworth Pitt, Swammire House, Bishop's Waltham, Hants
Hornby, Rev. Robert, Walton-le-dale, Preston, Lancashire
Birchall, Thomas, Ribbleton Hall, Preston, Lancashire
Knollys, Colonel, Blount's Court, Henley-on-Thames
Darnel, Thomas Smith, St. Neot's, Huntingdonshire
Smith, Charles H., Gwconlluynwyth, near Swansea, S.W.
Delfarins, M., Guernsey
Roe, Freeman, 70, Strand
Tredwell, John Clark, Oddington Grange, Bicester, Oxfordshire
Cracroft, Colonel, Hackthorn, near Lincoln
Thew, Edward, Lesbury House, near Alnwick, Northumberland
Linn, William, Broomhill Tile Works, Felton, Northumberland
Warry, Elias Taylor, Lyndhurst, Hants
Watts, Robert, Battle, Sussex
Langdon, Augustus, Cold Harbour, near Tonbridge, Kent
Carlich, Thomas, Chill Lodge, Tunstall, Newcastle, Staffordsh.
Williams, Thomas, Brecon, S.W.
Tilly, Harry Tobias, Tremough, near Penryn, Cornwall
Greaves, James, Redelive, near Buckingham
Smith, Chas. Robert, Collingbourne-Ducis, near Marlborough
Mitten, Leonard Pitt, Collinbourne, near Fovant, Wilts
Mason, Richard, Rowad, near Leominster, Herefordshire
Fowler, Marshall, Preston Hall, near Stockton-on-Tees, Durham.
Shrimpton, John, Easton, near Winchester
Davies, James, The Green, Aberystwyth, S. Wales
Dixon, Thos. John, Holton, near Caistor, Linc.
Molyneux, Jas. More, Loseley Park, near Guilford, Surrey
Shuter, T. Allen, Hooley House, Coulsdon, near Croydon, Surrey
Braudrane, John B., Beckenham, Kent
Bigg, John, Stanstead-Abbot's, near Hoddesdon, Herts
Hole, James, Knowle House, Dunster, Somerset
Hunt, John, Shirley, near Southampton
Cole, Thos. Henry, The Green, Wick, near Bath
Broderip, Edmund, Manor House, Cossington, near Bridgewater
Williams, G. M., Brocklesby, Great Limber, Linc.
Rawlins, George, Lee House, Romsey, Hants.
Wedlake, Mrs., Hornchurch, Essex
Whitaker, William, The Ash, Etwall, near Derby
Butler, John, Caerleon, Newport, Monmouthshire
Empson, Henry, West Ravendale, Binbrook, Spital, Linc.
Hutton, Thomas, Upton-Gray, Odiham, Hants.
Cock, William, Courtledge, Appledare, Tenterden, Kent
Sykes, Edmund, Mansfield Woodhouse, Notts.
Wooldridge, Henry, Meer-Stoke, Bishop's-Waltham, Hants.
Wooldridge, Jas. Wm., Webb's Lane, Wickham, Hants.
Cunynghame, John, Hensol, Castle Douglas, N.B.
Parkins, Edward, Chesfield Lodge, Stevenage, Herts.
Hart, Thomas, Wing, near Leighton-Buzzard, Beds.
Piper, John D., Colne-Engain, Halsted, Essex
Dixon, Thomas, Darlington, Durham
Coles, Lieut.-Col., Woodcote, Alresford, Hants
Rowland, William, Ramsbury, Hungerford, Berks
Bennett, Absolam, Mertyn-hall, Holywell, Flintshire

Mr. Langdale presented a new variety of Prolific Dwarf Pea; Mr. Wood, a specimen of Alexandrian Lupine; the Duke of Richmond, the second report of the Morayshire Farmers' Club, on the result obtained in the application of bones and sulphuric acid employed as a manure; Mr. Fleetwood, samples of the fibres of Sunflower stalks; Messrs. Kerr and Green, details on the sizes and prices of their iron-grated tile-ends, for preventing the entrance of vermin into drains; Mr. Baines, a communication on the modes of preserving milk; Mr. Stronge, a case of protracted gestation in a cow; Mr. Bellairs and Mr. Cochrane, papers on the economical collection of manures; Mr. Blurton, on his invention of a metallic churn; Mr. Charnock, papers relating to the Yorkshire Drainage Society; and Mr. Meyer, on the destruction of insects injurious to Agricultural crops. The Council then adjourned, over Ash Wednesday, to meet again on the 28th of Feb.

HIGHLAND AND AGRICULTURAL SOCIETY.

A monthly meeting of this Society was held on Feb. 7, in the Museum—Lord Rosebery in the chair. The first paper read was a report of analysis made of the ashes of peat from Berkshire, and from Kinblethmont, the seat of Mr. Lindsay Carnegie, in Forfarshire. Mr. Carnegie having tried, as a manure, the ash obtained from his own peat by burning, and finding it to produce none of the good effects attributed to the peat-ash of Berkshire, but on the contrary, to act as a poison to plants, Mr. Colvill undertook the analysis of the ash of both descriptions of peat, in order to detect any appreciable difference in their constituents, and this report is the result of his investigation: the elements of both ashes were found to be nearly alike, but the Kinblethmont ash contained sulphur and phosphorus in combination with iron, which the other did not, and which combination seemed to have produced the poisonous effects upon the plants observed by Mr. Carnegie. Besides this communication, a letter was read from Mr. Carnegie, descriptive of an experiment made by him with a manure denominated, by Mr. Colvill a double ammoniated magnesian salt, which is stated by Liebig to be an essential constituent of the Potato. The experiment was tried in the garden, and the result was as follows:—1 drill 30 feet long by 27 inches wide, with 2½ pints gave 4 stones 7 lbs., or 14 tons 6 cwt. per acre; the same extent, with 2 pints and 20 loads of dung per acre gave 4 stones 7 lbs., or 14 tons 6 cwt. per acre: with 2 pints only, it gave 4 stones 11 lbs., or 15 tons 4½ cwt. per acre; while without manure it gave 2 stones 4 lbs., or 7 tons 7 cwt. per acre. This substance is prepared by dissolving bones in muriatic acid, adding Epsom salts, and precipitating with excess of gas-liquor. Lord Strathmore then read a paper, in which, after noticing the neglect of peat-ashes, he described their value and utility as manure. It appeared from his Lordship's statement that the quantity, and most probably the quality, of peat-ashes, depend on the mode in which the peat is calcined. When peat is burned in the open air, a small quantity only of ash is obtained, some of the valuable properties of which are moreover suffered to be dissipated; but when the better sort of peat, which is that found at some distance below the surface, is cast at the proper season, dried, and burned in a kiln covered at the top, with a quick draught, the ash is greater in quantity and superior in quality, and the process is attended with little cost. When from 20 to 30 bushels of ashes obtained in this manner are spread upon an acre of green sward, they will produce as much herbage as a corresponding quantity of soot, at one-sixth the cost; and when such ashes are mixed with lime or fine sand, they are not only a superior top-dressing for upland or other meadows, and for Red Clover without Rye-grass, but they also prove a valuable manure for Carrots, Parsnips, or Mangold Wurtzel, on strong soil; his Lordship stated that one ton of peat, burned in a close kiln, would yield 14 bushels of ash. A communication from Mrs. Davies Gilbert of Eastbourne, Sussex, on the allotment system, was then read, in which she proves that in her system of allotting land five acres suffice for the support of one family. The last paper, which was read by Mr. J. Hall Maxwell, related to experiments with special manures, conducted by the land-steward of Mr. Fleming, of Barrochan. It formed the report for which the second premium of 30*l.* was awarded to the essay-competition of last year. We can only notice a few of the more important conclusions at which the author arrived. He found that the nitrate of soda and potash, when applied by themselves, or in mixture, are beneficial to Potatoes and hay; but when applied to grain crops, especially singly, they are positively

injurious in a moist climate, as, though the growth of straw is greatly increased by them, the sample of grain becomes lighter and otherwise deteriorated. He considers it probable that the silicate of potash would counteract this effect. Common salt, at a distance from the sea, is advantageous to grain crops as respects colour and plumpness, and also to Grass and hay, although it does not cause a rush of growth like the nitrates. Soot differs little from nitrates in its effects on Grass intended for hay, but the dealer in hay gives less price for hay raised by soot. Sulphate and muriate of ammonia have the same effect as the nitrates. Sulphate of soda and magnesia act differently, and will not pay in most cases when applied by themselves to Potatoes or grain, but they do well when mixed with the nitrates. Guano may be successfully applied to every species of crop in the field or garden, and it always proves a most powerful auxiliary to farm-yard dung.

ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

At the meeting of the Council on the 8th inst., the Secretary presented a return of the receipts and expenditure incurred at the late Cattle show at Belfast, whereby it appeared that the sum of 1762*l.* had been received by the sale of tickets to the entertainments, entrance to the show-yard, and fees upon the entry of stock, &c., and that a sum of 1593*l.* had been subscribed in different counties in the province of Ulster for the purpose, making a total of 3355*l.* received upon that occasion. It appeared also that the sum of 2954*l.* had been expended in the erection of the pavilion and show-yard, giving the entertainments, and in all the other incidental expenses, including a net sum of 500*l.* paid to the central society towards the payment of premiums, leaving a balance of 401*l.* in favour of the local committee, after defraying all the expenses of that great meeting. The Secretary stated that he had addressed a circular to the different members of the council, to the effect, that inasmuch as Mr. Hill, the owner of the prize Bull "Eden," at the cattle show at Belfast, had declined to comply with the proposal of the council for a re-adjudication, upon the terms long since communicated to him, the opinion of the full council should be taken as to what proceedings should be next adopted, for the purpose of bringing the matter to a final close; and that a special meeting of the council should be summoned for Thursday the 15th of February next, to take the subject into consideration. A letter was read from the Earl of Listowel, stating his conviction that the cause of Agriculture can in no way be so well promoted as by the employment of intelligent and competent Agriculturists upon private estates. A letter was read from Sir Richard O'Donnell, Bart., stating that it was his intention to place a premium of 12*l.*, or a gold medal or a piece of plate of that value, at the disposal of the Society, "for the landlord in Ireland who shall have thorough-drained on the farms of his tenants, or induced his tenants so to do, the greatest quantity of land, not less than 100 statute acres, upon Mr. Smith of Deanston's principles, in the years 1843 and 1844." Letters were read from the secretaries of various local societies, sending in the names of a sufficient number of members to the central society, to qualify them for the society's premiums this year.

FARMERS' CLUBS.

Bromsgrove.—At a meeting of this Club, held in the Town Hall, Bromsgrove, on January 30th, the Report for the year 1843 was read, from which it appears, that at the formation of the Club on the 20th June, 16 members were enrolled, but that the number has increased to 58. The objects proposed in its establishment were the diffusion of information on Agricultural subjects, and the promotion of Agricultural improvement. For the fulfilment of these objects, a meeting is held each month, at which some subject connected with Agriculture, is brought forward for consideration; elementary lectures on subjects connected with the theory and practice of Agriculture are occasionally delivered; and the surplus funds of the Club are applied to the purchase of books for the formation of an Agricultural Library. At the first meeting an introductory lecture was delivered by Mr. H. F. Fardon, "on the Advantages of Association for the improvement of Agriculture," in which the history of English agriculture was briefly given, its present importance enforced by reference to statistics, the duty and interest of nations and of individuals with respect to its improvement examined, the possibility of improvement urged, and the means of improvement inquired into; these are a remunerative price of produce, such equitable and proper arrangements between Landlord and Tenant as shall induce the latter to cultivate the ground in the best possible manner for the interests of both; and lastly, skill and knowledge in the farmer, to be communicated by proper education, and promoted by association. At the next meeting "the advantages of lime as a fertiliser of land" were considered. All plants grown by farmers contain lime in a greater or less degree, which they must absorb from the soil. In a caustic state lime combines with acids in the soil, and some of the compounds thus formed are serviceable as food to plants. It also decomposes certain noxious compounds of iron, &c., which frequently exist in the soil, but it differs in its action according to the state in which it is applied. It hastens the decomposition of vegetable and animal matter, and thus has a tendency to exhaust the soil of these ingredients.

Two lots of Potatoes were exhibited at the meeting by Mr. Elliot, each containing the produce of six roots. They were grown near together under similar circumstances, each receiving a dressing of farm-yard manure. When up and weighed, a small portion of carbonate of soda was sown between the ridges of one lot, at the rate of 150 lbs. per acre. The lot undressed with soda weighed 2 lbs. 2 oz.; that which received soda weighed 4 lbs. 6 oz. The subject of Seed Wheat, and the best method of pickling and planting the seed, afforded matter for discussion at several subsequent meetings, at which it was resolved, "That there is an adaptation in different varieties of Wheat to different soils; and that the practice of annually changing the seed from one soil to another is a good one; and that arsenic, sulphate of copper (blue vitriol), and salt, have been used with much success in the pickling of Wheat for the prevention of smut." A Paper on "Wheat Sowing" was communicated at one of the meetings by Mr. Richard Smith, of Upper Hall, near Droitwich. On strong clay soils, that moulder and heave after hard frosts, he approved of sowing broadcast and ploughing in from 2½ to 3 bushels per acre, the land being previously fallowed, because greater space is thus afforded for the roots. More seed, however, is thus required, and the crop cannot be so well cleaned. By drilling again, the seed is deposited at an equal depth, but the plants are crowded and the water is retained in the narrow channels made by the drill-share, particularly on strong soils and where the drilling is done lengthwise of the ridges. Mr. Smith recommends Lord Western's system of drilling, which is to have the heel of the common drill-share made four inches in width to scatter the seed that width in the row; a space of nine inches is left between the rows for tillage. Dibbling is the most perfect system, and will probably spread and become universal as population increases. All these remarks suppose the ground in a good state of cultivation, for if it is wet, foul, or poor, Wheat cannot be grown without loss.

Arrangements are about to be made by this club for the delivery of elementary lectures to the members, and the formation of a library has been commenced, and it is hoped that a lecture will shortly be delivered by Mr. Smith, of Deanston. It is also intended to institute a ploughing match. The report, of which the above is an abstract, having been read, Mr. Wright read a paper "On the Utility of Leases," advocating well-adjusted leases on Corn-rents. In arranging these rents, the price of Corn should be calculated on an average of a certain number of years. The rent of a particular year should not be founded merely on the prices of that year; otherwise, the tenant may have the highest rent to pay when he has the least produce. A resolution was adopted by the club, expressive of their opinion, that the only sound system for tenancy of land is on the principle of leases for 7, 14, and 21 years on Corn-rents.—*H. F. Fardon, Sec.*

West Firle.—At the annual meeting of this Society on Jan. 31st, the report for the past year was read. At the meeting, which took place on the 11th of September, the subject discussed was, "The advantages of drawing off Turnips, or feeding them on the ground." The chair was taken by John Ellman, Esq., president, who opened the evening's conversation by giving his views upon the subject, and upon this the resolution of the evening was chiefly founded, viz., "That no general rule can be laid down as to feeding Turnips on the ground, or drawing them off to be consumed in sheds or yards. That on dry light soils where sheep can feed them, treading is advantageous; but on more tenacious soils the Barley crop is frequently injured by the treading of sheep—still there can be no doubt, that in fattening sheep, one acre of Turnips will produce much more mutton when consumed in warm yards and sheds, than when fed on the open ground."

Miscellaneous.

Specific Manures are frequently capable of adding one or two substances only to the soil. It is evidently, therefore, of primary importance to ascertain, in the first place, whether the soil really requires the substance; for it is impossible that any specific can be valuable when applied to soil already abundantly supplied with the very substance it is intended thus to add to the land; in this instance, there must result either no effect or an injurious one, and in consequence, in both instances, disappointment. Let us take an example: nitrate of soda has been much and deservedly praised as a manure, and it has almost universally been declared to be equal to, and to act in a similar manner with nitrate of potash (saltpetre), in which case it would have the advantage of greater cheapness to recommend it. But in the above statement it is quite forgotten that the manure acts in two distinct ways: 1st, as a nitrate; 2d, as containing soda. Now, as regards the first action, viz., as a nitrate, these two salts can replace each other without the least difference in their action; but as respects the second mode of action, viz., the supplying the plant with soda, it is clear that they differ as distinctly as saltpetre does from common salt; and practice has proved this, for in more than one instance a considerable difference has been shown in the result obtained by the two manures. Thus, Prof. Johnston mentions the following result of an experiment at Erskine, near Glasgow, in 1841, upon Hay, with the two nitrates, in two different fields—the one being a light soil, the other a clay. In the light soil the nitrate of soda produced 3 cwt. more Hay per acre than the saltpetre, whereas, on the clay, the saltpetre exceeded the nitrate of soda by ¾ cwt. nearly; and it is well worthy of remark, that common salt, another compound of soda, was also employed in both cases, but yielded exactly 5 cwt. more upon the sand than on the clay; thus proving, we think, as well as a chemical analysis of the soil could have done, that the clay soil contained naturally more soda than the sand, and likewise probably that the sand was richer in potash. A similar case is likewise mentioned by Dr. Daubeny, of Oxford, where the nitrate of potash exceeded the nitrate of soda upon Wheat by upwards of 4 bushels per acre, and in which case the nitrate of soda produced no effect whatever; in fact, an equal portion of soil, without any top-dressing, produced 24 lbs. more grain than that upon which the nitrate of soda was used.—*Dr. Madden, on the Advantages of Extended Chemical Analysis to Agriculture.*

Improved Modern Husbandry compared with the Old System.—I. *Old System.*—Statement, showing the expense of the cultivation, together with the return from, an acre (Scotch) of cold, stiff soil, with a hard retentive subsoil, before improvement by draining, &c.; lease for 18 years; rent 25*s.* per acre.

Expense of a Six Years' Rotation.

	£	s.	d.
60 bolls lime, at 10*d.* per boll	2	10	0
Carting and spreading	1	10	0
First crop,—ploughing, seed, and harrowing	1	12	0
Second ditto ditto	1	15	0
Grass seeds and harrowing	0	10	0
Rent for six years, at 25*s.*	7	10	0
	£15	13	0

Return of a Six Years' Rotation.

	£	s.	d.
1st, 5 quarters Oats (with Straw)	5	0	0
2d, 5 ditto (ditto)	6	0	0
3d, 85 stones Hay, at 3*l.* per 100 stones	2	11	0
4th, pasture, at 20*s.*	1	0	0
5th, ditto ,,	1	0	0
6th, ditto ,,	1	0	0
	£17	11	0

The same repeated till the end of the lease, the land getting worse instead of improving.

Statement showing the expense of improvement, cultivation, and return from an acre of the same land, during a lease of 18 years; rent the same.

Expense of the first Six Years.

	£	s.	d.
Draining with tiles at 15 feet interval, 25 inches deep; tiles, 21*s.* per thousand	7	0	0
Lime, carting and spreading	4	0	0
Ploughing, harrowing, and seed	1	18	0
Second crop—ploughing, harrowing, and seed	1	16	0
	£14	14	0

Expense of Green Crop, viz.—

	£	s.	d.
Subsoil and other ploughings	4	0	0
Grubbing, horse-hoeing, and weeding	1	10	0
Dung, 10*l.*; lime, 1*l.* 5*s.*	11	5	0
	£16	15	0
Ploughing for Wheat and seed	2	6	0
Grass seeds, harrowing and rolling	1	5	0
Rent for six years, at 25*s.*	7	10	0
Interest on expense for draining for five years, at 5 per cent. per annum	3	15	0
	£44	5	0

Return of the first Six Years.

	£	s.	d.
1st, 8 quarters Oats (with straw)	10	0	0
2d, 8 ditto (ditto)	10	0	0
3d, Potatoes, 1-3d; Turnips, 2-8ds, at per acre	11	0	0
4th, 4 quarters Wheat, at 60*s.*	12	0	0
5th, 150 stones hay, at 3*l.*; foggage, 5*s.*	4	15	0
6th, Pasture, at per acre	2	0	0
	£49	15	0

Expense of the second Six Years.

	£	s.	d.
1st, Ploughing, harrowing, and seed	1	12	0
2d, Ditto, ditto, ditto	1	10	0
3d, Green crop without subsoil-ploughing	12	0	0
4th, Ploughing for Wheat and seed	2	4	0
5th, Grass seeds, harrowing and rolling	1	5	0
Rent for six years, at 25*s.*	7	10	0
Interest on draining, six years	2	2	0
	£28	3	0

Return of the second Six Years.

	£	s.	d.
1st, 9 quarters Oats (with Straw)	11	5	0
2d, 9 ditto ditto	11	5	0
3d, Green crop—at least	12	0	0
4th, 5 quarters Wheat, at 60*s.*	15	0	0
5th, 200 stones Hay, at 3*l.*; foggage, 5*s.*	6	5	0
6th, Pasture, at per acre	2	00	0
	£57	15	0

The expense and return of the third six years will be much the same as that of the second.

ABSTRACT I.—*Unimproved Land.*

	£	s.	d.
Expense during a lease of 18 years	46	19	0
Return ditto ditto	52	13	0
Profit per acre during the whole lease	5	14	0

II.—*Improved Land.*

	£	s.	d.
Expense of the first six years	44	5	0
Ditto second ditto	28	3	0
Ditto third ditto	28	3	0
	£100	11	0
Return of the first six years	49	15	0
Ditto second ditto	57	15	0
Ditto third ditto	57	15	0
	£165	5	0
Profit per acre during the whole lease	64	14	0

The above system of cropping is not one to be generally recommended; it is merely adopted as the basis of the above calculation because it is generally followed.—*Statement made by Mr. Smith of Deanston, at Bristol.*

Guano Contract.—The following is an extract from a translation of the Guano contract, to which much attention has of late been directed:—Art. 1. The company (Messrs. Quiros, Allier, and Co.; Gibbs, Crawley, and Co.; and Puimiroll and Co.,) has the exclusive privilege of exporting abroad the guano of the islands and other places where it is produced, as discovered, or to be discovered, for the period of four years, obligatory upon all the contracting parties from the present date. Art. 2. The quantity of 20,000 tons is assigned for the extraction of each year of the four years expressed in the preceding article, with the privilege of exporting the following year that which shall not have been exported in the year to which it corresponds; but, at all events, 80,000 tons shall be exported in the four years. Art. 5.—The state places for its capital in the company the guano at the value of 30 dollars the ton. Art. 6. The contractors place for their capital their industry and labour, and shall advance for account of the association all the expenses of getting the guano, loading, insurance, freightage, commission of shipping and of sale, and other expenses caused by the business as well in Peru as in the markets of consumption. Art. 7. From the produce of sales of the guano are to be deducted the costs, freights, insurances,

expenses, &c., and the capital assigned of 30 dollars per ton, and the result will give the amount of profit or loss, which is to be divided in the manner following: three-fourth parts for the State, and one-fourth part for the contractors. Art. 15. For the present the extraction of guano is alone permitted in the Island of the North (*Isla del Norte*), in those of Chincha. Art. 22. The exportation of guano being, according to the first article of this contract, the exclusive privilege of this company, the Supreme Government binds itself not in any case to dispose of any quantity whatever, whether in the shape of recompense, sale, gift, or in whatever mode; nor to permit its exportation by any person not of the association during the four years applicable to the contract.

Notices to Correspondents.

Our Correspondents will oblige us by not mixing together Agricultural and Horticultural questions, and by writing them on one side of the paper only. Such precautions can give them no trouble, and will save us a great deal.

Account Book.—*A Subscriber and Farmer.*—If you or the publishers will send or lend us a copy of the Work referred to, we shall be happy to give an opinion of it.

Beans.—*A Yorkshire Subscriber.*—You might with advantage mix guano with the dung before putting it in the drills, at the rate of two cwt. to such a quantity as you intend to put on an acre.

Best way of applying Soluble Salts to Land.—*An Amateur.*—Dissolve them in water. The least quantity which will dissolve the weight of salt you wish to apply to an acre, will do equally well with any larger quantity, provided you can spread it uniformly over that extent of land. If your water-cart will, when in ordinary work, spread so many gallons per acre, then your plan is, to dissolve in that number of gallons the quantity of the salt which you wish to apply per acre. These salts may be advantageously applied now. You had better give your heifers some Swedes or M. Wurzel along with the Hay.

Books.—*North Cheam.*—Low's "Elements of Practical Agriculture" is the best work on Farming in our language. Cuthbert Johnson's "Encyclopædia of Agriculture" is one of the best of its class.

Breed of Pigs.—*S. Frocklor.*—We do not know the Rudgewick breed of pigs, but perhaps some of our readers, seeing this notice, may be able to inform you through us whereabout "in Surrey or Sussex" they are to be obtained.

Burnett's Antiseptic Solution.—*A Subscriber.*—We do not know it.

Dibbling Oats.—*L. T.*—We never heard of Oats being dibbled. What is true of Wheat on this subject must, however, be true also of Oats; the only question is whether the less value of seed saved will more than pay the same additional cost of this mode of sowing.

Essay on Drainage.—*E. Barnard.*—Mr. Arkell's Prize Essay is not published in a separate form.

Fatting Oxen.—*Gorge.*—If you intend giving your cattle *all* these things, let them have, say, 2 lbs. of oil-cake, 5 lbs. of Barley-meal, and 5 lbs. of Hay-chaff, with Swedes *ad lib.* Mr. Warners, of Walsingham, Norfolk, is the person to apply to on a subject like this; he manufactures a composition for fattening cattle, by which it is said that beef may be grown more cheaply than by any of the ordinary methods of feeding. Foreign oil-cake is quoted at per ton, and not at per 1000 cakes, because the size of the cakes differs very much. You will find a plan of a piggery at No. 3 of the *Agricultural Gazette*, reference to the letters on which having then been accidentally omitted we now supply. F, F, F, F, farmyard; R, R, R, roads; A, A, A, shed, with yard in front for store-pigs; T, tank for drainage of sties, yard, and sheds; S, steaming-room; the double row of sties below the steaming-room are for the fatting pigs, two being fed in each; and the single row at one end of the steaming-room are for a boar and six brood sows.

Gas-Lime.—*A. B.* will find information on this point if he looks over this section of this and previous Nos. of the *Gazette*.

Gas-water.—*Wem.*—The salts of ammonia in gas-water will differ with different qualities of coals used for making the gas. In some cases the liquor contains much sulphate and but little carbonate; whereas in others the latter predominates, and when this is the case, and gypsum is at hand, the sulphate of ammonia may be produced by its agency (the mineral being added in powder to the liquid); but the addition of sulphuric acid is the best and certain road to the formation of this salt, in whatever state the ammonia exists. Boil to a pellicle and crystallise.

Glossary of Scientific Terms.—*Literalis.*—If we understand you right, this is what you want. We shall take the subject up in some future Number of our Paper.

Gorse.—*Charles Etheredge.*—Information on this subject has been published in this and last Paper. We hope to be still more explicit on the points you refer to shortly. Mr. Ransome has a Gorse-crusher, and a Chaff-cutter applicable to the cutting of Gorse may be had at Utley Iron Works, Gloucestershire.——*Tuesday.*—Furze grows in nature on "wettish clay land," perhaps because it has been eradicated from all the better description of land. It prefers a dry loamy sand.

Horse-ponds.—*J. R.*—Undoubtedly, cattle should be supplied with *clean* water. We shall endeavour to obtain for you a statement of the *medicinal* properties of that which we often see in horseponds, discoloured by the runnings from the stable, cow-houses, &c.

Lime.—*Creta-cremenla.*—You state the results of an experiment which was favourable to the plan you propose, facts, such as you detail, are safe as guides, though present theory may not explain them. In applying lime to your meadow-land, make a compost of it when caustic, with a lot of vegetable mould, and let it remain till it slakes. You may apply so much per acre of the compost as contain, say 100 bushels of lime, early in spring on your grass-land, and it may also be applied with advantage to your arable land. Clays generally require a greater dressing of lime than light soils.

Liquid Manure.—*C. E. F.*—Your tank might be 6 feet deep and 9 in diameter, flagged or paved at bottom, and with ordinary stone and mortar walls. It is certainly worth your while to adopt means of this kind to save the liquid manure.

Manures.—*Economist.*—Cloacine should be mixed with black turf-ashes and dry earth, and after a while you will be able to drill it.——*Constant Reader.*—Horse-flesh must be greatly more valuable than woollen rags as manure, but *how much* more so we do not know. Bones are generally spread or drilled by themselves without mixture. Sulphuric acid would not reduce large bones to a pulp (see article on this subject in our Home Correspondence). We shall answer your question about tithe-charge next week.——*W. H. B.*—Substances employed to mix with artificial or condensed manures are of two kinds: viz., such as are intended merely to dilute them as it were, so that by their addition, there being a larger bulk to apply to the land, we may be able to do so more uniformly; and such as really increase the value of the manures they are mixed with. The sand you propose to mix with the guano may belong either to one or other of these two classes: if it be ordinary sea-sand, it is of the first kind, and earth from the surface of the field would answer your purpose much better; but if it be such as is found on the northern coasts of Cornwall, 6s or 7s per cent. of which is carbonate of lime, the sand itself being chiefly comminuted sea-shells, then it belongs to the second class, and may be usefully employed as you propose, especially if the land you are about to manure be deficient in calcareous matter. In the latter case you may advantageously apply six or eight cart-loads of this sand per acre, and you will have to mix your 2 or 3 cwt. of guano through it all.

Management of Grass-Land.—*Warrington.*—We always feed our young seeds down close in autumn with sheep, and consider the manuring they thus receive does them good; and probably this management would suit permanent pasture also.

Marl.—*J. Yorke.*—Your specimen will probably be valuable as a top-dressing for land deficient in calcareous matter. It appears to be almost wholly carbonate of lime; but you will find, by reading Sprengel's articles in this Paper, that the value of marl frequently depends on the existence in it of matter, whose presence can only be detected by a tedious analytic process.

Market for Feeding Stock.—*J. Clark.*—Romford-market, in Essex, is one of the best in England for stock; during the autumn and spring months great numbers are offered weekly for sale, and are mostly purchased for fattening.

Moss-land.—*A Town Farmer.*—Judging merely from the information you give, we advise you to pare and burn this land; break it up, take a crop of Turnips off it, working the land well during their growth, and lay it down to Grass along with the succeeding crop of Barley. It is no good trying to *tear* the Moss out.

Peas.—*Gwyn.*—Peas prefer light soils, but they may be grown on stiff soils, like the Bean; if, after ploughing, your land gets well frozen, then it will harrow down well, and you may drill the seed in with the Suffolk drill, in rows, say, 9 inches apart.

Potatoes.—*A Constant Subscriber.*—Place the dung in the rows, and if it is well rotted, you may use the horse-hoe to mix it with the bottom earth of the furrow. Plant the Potatoes in the loosened earth, and then hoe or plough the drills down to cover them. It will take about seven sacks of Potatoes to plant an acre.

Quantity of Guano per Acre.—*Tuesday.*—In ordinary cases, 3 cwt. per acre. Mix it thoroughly with the soil before sowing. The quantity required depends upon the present condition of the land.

Soils.—*J. Marshall.*—If your soil is similar in character to the specimen No. 1, the clay, then we doubt not that it would be greatly improved by a dressing of No. 2, the calcareous sand you sent. The clay, No. 1, is not a marl; it contains hardly any lime, and would do very well to make tiles and bricks of. No. 2 contains at least 30 per cent. of lime; and rather than send 12 miles for lime, you had better try a good dressing of this which is at hand. If you resolve to do this, please to let us know the result of the application. As for the sulphureous smell you speak of, the cause might be ascertained by an accurate analysis of the material from which it arises; *i. e.*, if you are not mistaken in its existence.

Steeping of Seeds.—*Gentleman Farmer.*—Mr. Campbell informs us that "after steeping the proper time, the grain is to be taken out and spread to dry under a current of atmospheric air (not by heating). The time of steeping for Wheat may extend to 84 or 90 hours; for Oats, 68 to 72 hours; for Barley, from 58 to 60 hours; for Grass-seeds, from 14 to 16 hours; for Rye, 70 hours; for Beans and Peas, from 18 to 20 hours; for Turnips and Rape-seed, from 10 to 12 hours. The grain must not be kept in a wet state after being taken out of the liquid; but the drying must commence immediately. When sown, much less seed must be used than is commonly done, as the plants tiller into numerous stems."——*Oakley.*—The Leading Article in No. 4, and Mr. Campbell's answers above, will probably serve your purpose. We doubt if soaking Potatoes would be beneficial. The experiment had better be tried now with one in a flower-pot; see if it sprouts vigorously there, before trying the plan in the field.

Stall-feeding.—*G. C.*—Next week.

Stall-feeding Oxen.—*W. T.*—In East Lothian it is generally considered better to adopt the system of hamels, as they are termed, *i.e.*, to place fatting oxen two and two in small yards, each with a shed, rather than tie them up singly in a feeding-house. By this means, in addition to the greater comfort of the animals, and the consequent greater rapidity of fattening, the farmer is enabled to get his straw trod into dung more rapidly.

Swedes on Clay-land.—*H. S.*—We suppose the land is dry. Cultivate it and manure it in autumn, and leave it rough for the winter's frost. Scarify and stir it 4 or 5 ins. deep in spring, as often as it is necessary to bring it to a tilth; beat it up towards the end of May in drills 26 ins. wide, and sow.

Task work.—*Midland County.*—We shall endeavour to put your plan in execution.

Toll Exemption.—*E. A. P.*—We think the decision of the Borough Magistrates was wrong. The exemptions in the Acts are to be construed liberally in favour of Agriculture; and without resorting to a forced construction, we think the peat under the circumstances described would be exempt under either of the terms, "soil" or "manure."

Trench Ploughing.—*A Subscriber.*—It is rarely advisable to plough below the full depth of the active soil. Your best plan, if your land is well drained, is to subsoil-plough it once every fourth year, and by and by the soil will become mellow to a great depth, and then you may trench plough it with advantage. Your suggestion with regard to an article on manure shall be attended to.

*** As usual, many communications have been received too late for answering this week.

Markets.

SMITHFIELD, Monday, Feb. 12.—Per stone of 8 lbs.

	s. d.	s. d.		s. d.	s. d.
Best Scots, Herefords, &c.	3 10	4 2	Best Downs & Half-breds	4 2	4 6
Best Short Horns	3 6	3 10	Best Long-wools	4 0	4 4
Second quality Beasts	3 0	3 4	Ewes and second quality	3 6	3 10
Calves	4 0	4 10	Pigs	3 0	4 4

Numbers.—Beasts, 2760; Sheep, 23,630; Calves, 64; Pigs, 270.

Although the supply of Beasts continues very moderate, trade is heavy at our late quotations, in consequence of the large arrivals and dull sale at the dead markets. Mutton is again in less quantity, and a brisk demand at an advance of full 2d per 8 lbs. on heavy woolled Sheep; but the best Downs do not make a proportionable progress, there being much greater numbers of them and of Half-breds from Norfolk, than of other kinds, and it is only in very selling ones that our highest quotation is realised. Veal is a heavy trade, at a reduction of fully 2d per 8 lbs. Pork remains steady.

FRIDAY, Feb. 16.

We have to-day a very heavy trade in all kinds of stock, at reduced prices. A large supply of Beef and Mutton, on seasonable weather, and very depressed state of the dead markets, have combined to produce this effect with regard to those articles. The best Beef cannot be quoted at more than 3s 8d to 4s, the best Downs, &c., 4s to 4s 6d; and other qualities suffer in the same proportion. Calves are not quite so plentiful, but we cannot quote any advance, it being difficult to make 5s per 8 lbs of anything.

Numbers.—Beasts, 3360; Sheep, 20,950; Calves, 100; Pigs, 310.

41, West Smithfield

POTATOES.—Southwark Waterside, Feb. 12.

During the early part of the past week our market was depressed, and there was but little demand, except for the best samples; other lots moved heavily, at terms of this day week. The demand for Early Devons has been very limited, the trade is gone off them very considerably, and 70s must still be regarded as nominal. The last two or three days the holders of the best Scotch Reds have been asking 70s, but few sales have been effected at that price; yet should we have a continuance of cold weather, it is expected that the annexed prices will be maintained.

York Reds	- - -	60s to 70s	Kent and Essex Whites	- -	55s —
Perth	- - -	65 70	— —	Kidneys -	65 70s
Early Devons	- - -	65 70	Wisbeach Kidneys	- -	65 —

Kingsford and Lay.

MARK LANE, Friday, February 16.—The Market has been scantily supplied with English Wheat since Monday, which sold at the full prices of that day. Free Foreign is held for an advance, which renders the transactions limited; there is not much doing in Bonded, but the few sales effected have been at prices rather exceeding the late rates.—Fine Malting Barley is more in request, but we cannot alter our quotations.—Beans and Peas remain without alteration.—Oats are fully as dear, but business is not extensive.

Kingsford and Lay.

COVENT GARDEN, Feb. 16.—The supplies of most kinds of Fruit and Vegetables, during the week, have been tolerably good, and trade continues much the same as in our last report. Pine Apples are selling at nearly the same prices as last week, and little alteration has taken place in those of Grapes. Good dessert Pears continue to get scarce; Beurre Rance do not ripen well this season and are very liable to decay. English-grown kitchen and dessert Apples are rather scarce, and are advanced a little in price; but foreign ones, consisting principally of common sorts, are abundantly supplied. Oranges are offered at nearly the same prices as last week. Lemons bring from 6s. to 14s. per 100. Chesnuts are offered at nearly the same prices as in our last report. Among Vegetables, Cabbages are scarce; Brussels Sprouts are selling at from 1s. 6d. to 3s. 6d. per half-sieve. Broccoli continues scarce. French Beans are much the same as in our last report, as are likewise Greens. Celery has a little advanced in price during the week, as has also Endive, the latter is selling at from 1s. 6d. to 3s. per score. Seakale is good and sufficient for the demand. Asparagus is offered at from 2s. to 10s. per 100. Lettuces are selling at nearly the same prices as last week. Cucumbers bring from 4s. to 8s. each. A few of the Early Horn Carrot are offered at from 4d. to 8d. per bunch. Cut flowers chiefly consist of Erica gracilis, Burchellia capensis, Epiphyllum truncatum, Leschenaltia tricolor, Æschinanthus grandiflorus, Azaleas, Acacias, Rhododendrons, Camellias, Cinerarias, Tulips, Primulas, and Roses.

FRUITS.

Mark Fortnum.

RANUNCULUSES.

J. SUTTON AND SONS beg to offer the following:—

50	choice Sorts, by name, a pair of each	£1	5 0
50	do. one root of each	0	15 0
25	do. a pair of each	0	13 6
25	do. one root of each	0	8 6
Double Italian Tuberoses, per dozen		0	4 0
Ferraria, or Tigridia pavonia, very strong Roots, per dozen		0	2 6

NEW FLOWER SEEDS.

75	most showy hardy Sorts (selected)	£1	0 0
50	do.	0	15 0
25	do.	0	7 6

KITCHEN GARDEN SEEDS.

Messrs. SUTTON and SONS respectfully solicit and recommend attention to the Collections of NEW KITCHEN GARDEN SEEDS which were advertised by them in the *Gardeners' Chronicle* of Dec. 30th and Jan. 6th. The Seeds are safely packed for conveyance to any distance, as they receive many Orders from Scotland and Ireland.

N.B.—Parcels delivered free to any of the Railway or Packet Offices in London, or to any part of the Great Western Railway, within 70 miles of London.

Catalogues may be had *gratis* at the Seed-shop, Nos. 7 and 8, Market-place, Reading, Berks.

KENSINGTON NURSERIES.

RICHARD FORREST AND Co. beg leave respectfully to direct attention to their GENERAL NURSERY STOCK, which was never finer than this season, especially the extensive and correctly-named Collection of FRUIT-TREES.—See Advertisement for Nov. and Dec. 1843, of this Journal.

In consequence of the Lease of one of their Nurseries expiring, and being required for other purposes, R. F. & Co. deem it necessary to assure their Customers everywhere that it will not occasion the slightest interruption in their business. The Shop, Warehouses, &c. will remain undisturbed, and the ample provision which has been made in the adjoining Nurseries for this little change will insure the same supply, and attention to all the Customers, which they have uniformly experienced. To those who have visited the Nurseries recently, these observations are perhaps unnecessary; but to those who have not had an opportunity of witnessing the improvement of their Stock, R. F. & Co. consider this slight notice necessary to counteract any prejudice that might be raised in the minds of their numerous friends throughout these kingdoms and elsewhere.

TO GARDENERS AND BOTANISTS, &c.—As young Gardeners have often great difficulty in getting their specimens of the beautiful tribe of MOSSES correctly named, the Advertiser offers to assist them in the following manner:—If 20 of such will send their names and addresses as subscribers to the amount of 7*s.* 6*d.* each, before March 10th, he will prepare 20 packets of Mosses, each containing 100 correctly named species, which will be sent, Post free, one to each subscriber, in April. A selection of examples of HEPATICÆ, LICHENS, FUNGI, ALGÆ, and ZOOPHYTES, will be added to increase the usefulness of each packet. The money to be sent by Post-office order.—Address, W. GARDINER, 40, Overgate, Dundee. The offer not to be repeated if unfavourably received.

W. G. has also prepared a few 5*s.* packets, including 60 species of SCOTTISH ALPINE MOSSES, LICHENS, and HEPATICÆ; a few 5*s.* packets of 30 named ZOOPHYTES or ANIMAL PLANTS; and a few 5*s.* packets containing selections of ZOOPHYTES, ALGÆ, and ALPINE MOSSES, LICHENS, and HEPATICÆ. Can be sent by Post. Early application necessary.

THE BRITISH QUEEN AND PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above two new Varieties, the merits of which are thus noticed in the *Gardeners' Chronicle*. "THE BRITISH QUEEN on light soils, is the best of all kinds, and will drive Knight's Tall Marrow out of the garden." "THE PRINCE ALBERT, which has been cultivated in the Garden of the Horticultural Society during the season, produced Peas fit for the table *ten days earlier* than any other variety sown at the same time." Both varieties may be had in packages at 3*s.* 6*d.* each, at W. J. C.'s wholesale Establishment, Newcross, or the Bedford Conservatory, Covent Garden.

SHILLING'S EARLY GROTTO PEA.

J. AND S. SHILLING have succeeded in raising the above PEA, the Early Frame Pea, impregnated with the Grotto or Oyster Marrow, which they, with confidence, recommend to the Public generally, being quite as early, and nearly double the size of any other Pea in cultivation. Quite hardy, will stand the winter well, and a good bearer; the pod large and long. They would particularly recommend it to the attention of Market Gardeners. Price 3*s.* per quart; 10*s.* per gallon; 17*s.* 6*d.* per peck; 30*s.* per half-bushel; 2*l.* 10*s.* per bushel. Agents:—Messrs. FIELD and CHILD, 119, Lower Thames-street, London; Messrs. W. and J. NOBLE, 152, Fleet street; Mr. KERNAN, 4, Great Russell-street, Covent Garden; Messrs. HURST and McMULLEN, 61, Leadenhall-street; Messrs. GRAY, ADAMS, and HOGG, Kensington; Mr. T. D. WATKINSON, Market-place, Manchester.—Northwarnborough Nursery, near Odiham, Hants.

GENUINE PERUVIAN & BOLIVIAN GUANO
ON SALE, BY THE IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
GIBBS, BRIGHT, AND CO., LIVERPOOL AND BRISTOL.
47, Lime-st., Jan. 31, 1844.

GUANO, PERUVIAN, &c.—The above Manures, also Potter's Guano, Nitrates of Soda and Potash, Gypsum, Bone-dust, and all other Chemical Manures of known value may be had of the undersigned, on the best terms, for cash.

Lists of Prices, with synopsis of mode of use, on applications to MARK FOTHERGILL, 40, Upper Thames-street, London.

ON SALE, in any quantity, PERUVIAN and BOLIVIAN GUANO, genuine as imported,—Apply to COPESWORTH, POWELL, and PEVOR, London; EDWARDS, DANSON, and Co., Liverpool; or WILLIAM J. MYERS and Co., Liverpool, the Importers.

MANURE FOR GRASS, &c.—POTTER'S GUANO.
Testimonial of Lord Zetland, Dec. 2, 1842.

POTTER'S GUANO, 2 cwt. per acre, yielded of *Hay*	2 tons	8 cwt.
Peruvian Guano, 2 cwt. per acre, yielded of *Hay*	1 "	18 "
Difference in favour of Potter's Guano		10 cwt.

BEAUTIFUL FLOWERS. — POTTER'S CONCENTRATED LIQUID GUANO, in quart bottles, 1*s.* 9*d.* each, at the principal Chemists and Seedsmen in town and country.

"I used POTTER'S GUANO on my Pansies; they were *much larger* than I ever had them before, and remained in full blow longer than I ever recollect. JOHN RITSON, Sunderland."

"POTTER'S GUANO will convert your desert into a paradise."—Professor LINDLEY, in *Gardeners' Chronicle*, 1843, p. 560.

Works, 28, Upper Fore-street, Lambeth.

For further testimonials see this Paper of the 6th Jan., 1844.

TO GARDENERS AND AGRICULTURISTS.

SUPER-PHOSPHATE of LIME is capable of producing a more rapid vegetation in Plants than any substance known. It may be had at Mr. LAWES' Factory, Deptford Creek, price 7*s.* per cwt.

Phosphate of Potash		15*s.* per cwt.
" Soda		12*s.* "
" Magnesia		9*s.* "
" Ammonia		1*s.* per lb.

GUANO.—Having made arrangements with Messrs. WM. JOS. MYERS and Co., of Liverpool, for a Cargo of this Manure direct from Peru, the Subscribers will bring the same into Berwick-upon-Tweed in all February and March.

Haddington, Feb. 9, 1844. BANKS and SON.

Note.—As this will be one of the very few cargoes from the Pacific, whose charterparties will admit of their discharging on this coast, BANKS and SON would recommend intending purchasers to apply for what they may require as early as possible.

TO AGRICULTURISTS.—IMPORTANT DISCOVERY.
"Quid faciat lætas segetes"—VIRGIL.

THE CORN-PRODUCING LIQUIDS.—"One of the most extraordinary exhibitions in the yard (at the late Agricultural Show, Dundee), was that presented by Mr. JAMES CAMPBELL, of the Dundee public seminaries. It consisted of magnificent plants of Oats and Barley, grown from seed which had undergone a certain chemical preparation, and without the aid of any manure whatever.

"Such a mode of culture is at variance with all practical experience; but Mr. CAMPBELL declares that his prepared seeds, which have produced these strong, healthy plants, were sown by him on land which, to his certain knowledge, had had no manure of any kind for eleven years; and he declared himself quite ready to verify his statement by experiment, and said he was willing, at any time, to impregnate with his chemical preparations the seed which any member of the Society should send to him for that purpose, so as to enable gentlemen to satisfy themselves fully as to the efficacy of this wonderful mode of culture."—*Journal of Agriculture, October*, 1843.

In this discovery is actually realised that boast of science, which some years ago prophetically asserted, that the time would soon come when one might carry in his pocket matter sufficient to manure an acre of land.

After impregnation with these liquids, the seed possesses within itself elements which not only afford additional nourishment to the grain during the progress of germination, but communicate to the expanding vessels of the plant an aptitude to absorb food, both from the soil and the atmosphere.

Of one specimen of Oats exhibited, the average produce of 33 seeds was 1600 grains from each, or a total of 52,800 grains, weighing 48 lbs. per bushel.

The produce of Barley was an average of upwards of 500 grains from each seed sown; and of Wheat sown on 5th July, and taken up on 8th August, to be exhibited, the result was, that while the unprepared seeds gave plants with two, three, and four stems only, the impregnated grain yielded plants with nine, ten, and eleven stems.

The material for these liquids, at the following prices, may be had of the following Agents.

Wheat	material for one gallon	2*s.* 6*d.*
Barley	do.	2 0
Oats and Grasses	do.	1 6
Beans and Peas	do.	2 0
Turnip and Rape-seed	do.	2 6

Agents.—Messrs. GEORGE GIBBS & Co., Down-street, Piccadilly, London; JAMES HADEN, Ironmonger, Warminster, Wilts; JOHN CAMPBELL, 5, Mersey-street, Liverpool; E. R. CROUCH, Newcastle-on-Tyne; SAMUEL WALDIE, Carlisle; W. W. EYRE *Agricultural* Office, Berwick; Messrs. P. LAWSON & SON, Edinburgh; DRYSDALE & Co., Glasgow; DRUMMOND & SON, Stirling; and DICKSON & TURNBULL, Perth.

One third, or even one-half less grain, is required for seed than is commonly used; and twelve gallons will impregnate eight bushels of grain; for the operation may be repeated in the residual liquid with additional measures of grain, as not more than one tenth is absorbed in each operation.

Particular printed instructions for using the liquids will accompany invoices. No order under 20 gallons will be supplied.

1, Dudhope-street, Dundee.

BURBIDGE AND HEALY beg respectfully to inform the Horticultural world that they are quite ready to supply their new BOILER, of every size. They have not fixed a sufficient number to warrant them in stating that what they put forth as the qualities of their Boiler and Furnace arrangement may be perfectly relied upon: they have put up one at the Horticultural Gardens, where B. and H. believe it is considered to answer as represented; they have also fixed it in connection with a new description of Iron Tank, which combines the qualities of the round pipe and the open tank, which may be pronounced the perfection of a Heating Apparatus for Horticultural purposes, particularly for Graperies, Epiphyte-houses, Melonpits, &c., &c. The arrangement is such that any gentleman or gardener may have the whole constructed so as to be put together with the greatest facility by the gardener, first sending a correct plan to 130, Fleet-street. A Prospectus may be had detailing the prices, &c.

LIQUID MANURE.

PUMPS of a Superior Construction, fixed and portable, for Liquid Manure. Garden Pumps, Hydraulic ditto, and Pumps for deep wells. Also Pumps for Ships, Barges, Tanners, Soap boilers, Brewers, &c. Well Digging and Boring executed. BENJAMIN FOWLER (late George Turner), 63, Dorset street, Fleet-street.

THE URATE of the LONDON MANURE COMPANY, 5*l.* per Ton. It is with the greatest satisfaction after three years' experience, the Company are enabled to recommend the above as one of the best manures for Barley, Oats, Spring Wheat, and more especially Turnips. By promoting a rapid growth of the latter it secures a full plant, at the same time producing a great weight per acre, and extending its beneficial effects to the succeeding crops. The Urate may be sown broadcast, or which is preferable, by the drill, at the rate of one ton to three acres, and it is desirable it should not be placed more than two inches below the surface. As a top-dressing for Wheat the Urate has been used with great advantage. Gardeners and Florists will find it very useful for Dahlias and other roots. Full particulars and Testimonials will be forwarded on application. Genuine Peruvian Guano; Phosphate and Sulphate of Ammonia; Gypsum and every other artificial Manure.

EDWARD PURSER, Secretary, 40, New Bridge Street.

NETTING, BUNTING, and SCRIMS, for EFFECTUALLY PRESERVING the BLOSSOM of FRUIT-TREES from FROST, in convenient quantities and at small cost, at BENJAMIN EDGINGTON'S Marquee and Rick Cloth Manufactory, No. 2, Duke street, Southwark; and 209, Piccadilly, London.

"We understand from some of our friendly horticultural acquaintance, that wherever Bunting Screens have been employed, the wall-fruit has set in the finest manner, hence we again recommend this fabric in preference to any other."—*Bell's New Weekly Messenger.*

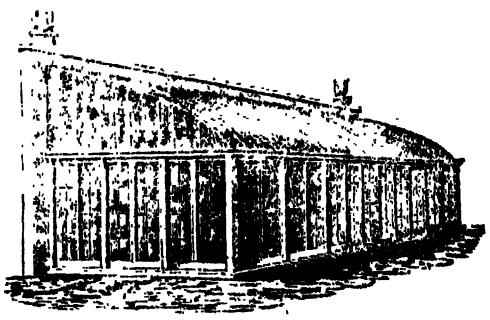
N.B. Some of the canvas used at the Smithfield Club Cattle Show to be sold as second hand, at moderate price, suitable for Rick Cloths, &c.

Just ready, price 1*s.*

PRACTICAL HINTS to Practical Men, on NEW and OLD MANURES, by JOHN DODDRIDGE HUMPHREYS, Esq., author of the Electro-Physiology of Man, &c., &c. Full information is here given as to the advantages of the New Manure called HUMPHREY'S FARMER'S COMPOUND, which is not subject like the Guano to be washed out of the soil, but unites the progressive action of the natural with the highest fertilising powers of the best chemical agents. Wholesale Agents, DAVY, MACKRODDO, and Co., 100, Upper Thames-street, London.

LONGMAN, BROWN, GREEN, and LONGMANS.

TO COLONISTS, AGRICULTURISTS, &c.—Mrs. MARY WEDLAKE, widow of the late Mr. THOMAS WEDLAKE, of the Original Iron-foundry and Agricultural Implement Manufactory, established forty years, at Hornchurch, near Romford, Essex, and of 118, Fenchurch-street, London, begs to inform the friends of her late Husband that she continues to Manufacture all kinds of Agricultural Implements, for the invention of which he was so often honoured with the medals of the Royal Society of Agriculture, and which obtained for him so high a distinction among the Farmers of England and British Colonists. Being assisted by men of talent in the Manufacture of these articles, she is in hopes of deserving the high repute this Establishment has so long enjoyed, and now solicits respectfully a continuance of the patronage of the numerous friends of her late husband. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, 118, Fenchurch-street, viz.—



Patent Hay-making Machines	Subsoil Ploughs
Winnowing Machines	Horse-power and Hand-thrashing Machines
Dressing Machines	Patent Horse Rakes
Patent Chaff-cutting Machines	Scarifiers
Oil-cake Crushers	Drills of all kinds
Double-action Turnip Cutters	Park Fencings, Hurdles
Flour Mills	Furnace Bars
Bean Mills	Cast Iron Horse Racks
Railway Wheels, Vacuum Pumps	Kitchen Ranges
Patent Essex Ploughs, 30 different sorts	Stoves, Fenders

*** Castings to any pattern.

☞ *For a more detailed List, see Johnson and Shaw's "Farmers' Almanack" for* 1844.

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch-street, London: or, Original Iron Foundry, Hornchurch, Essex.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c. &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL-ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices, in consequence of the present depressed state of the Iron Trade.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public, or Private Buildings, &c., with COTTAM'S PATENT, or ROGERS' BOILERS. After 15 years' experience, and having fixed upwards of 1500 Apparatuses for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale. For the convenience of those who wish to fix their own Apparatus, they have affixed the following low prices:—

	£	*s.*	*d.*
Cottam's Patent Boiler, 18 inch	2	15	0
Rogers' Boiler, small size	1	17	0

Larger in proportion.

Hot-water Pipe, at 2, 3, and 4 inches, at reduced prices.

GARDEN ROLLERS 18 inches long, 34*s.*; 20, 44*s.*; 22, 50*s.*; 24 inches, 60*s.*; 26, 75*s.*; 28, 84*s.*; 30, 105*s.* each.

CAST-IRON RICK-STANDS, 2 feet six inches high, 5*s.* 9*d.* each.

Garden Engines, Mowing Machines, Garden Chairs, Superior Garden Tools of all kinds, Garden Vases and Pedestals in great variety, and every description of Horticultural Articles, Agricultural Implements, and Furnishing Ironmongery; Dr. Arnott's Stoves, Anglo-Belgian Cooking Stoves, Broiling Stoves. The above low prices being on account of the depression in the Iron Trade, are subject to future alterations.

STRONG IRON HURDLES, 3 ft. high out of the ground, 6 ft. long, with five horizontal bars, weighing about 36 lbs., 3*s.* 6*d.* each.

Light Cattle Hurdles, 3 ft. 6 in. high, weighing	42 lbs.,	4	0 "
Strong do. do.	do. 45 lbs.,	4	4 "
Ox Hurdles, 4 feet high,	do. 60 lbs.,	5	6 "

BEST WIRE, for STRAINED WIRE FENCING, at 9*s.* per bundle of 150 yards each. Uprights for ditto, 7*d.* each. The Improved continued, and every other kind of Fencing, Fancy Wirework, &c.

HAND-GLASS FRAMES for Cucumbers, &c., 18 inches square, 3*s.* 6*d.*; 20 inches, 4*s.* 6*d.*; 22 inches, 5*s.* 6*d.* each.

CAST-IRON FLOWER-STAKES, 4 ft. four out of the ground, 7*s.*; 5 ft. 9*s.*; 6 ft. 11*s.*; 7 ft. 13*s.*; 8 ft. 20*s.* per dozen.

SHOW-ROOMS at the Manufactory, No. 2, WINSLEY-STREET, where every information may be obtained.

The TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

In small 8vo, Second Edition, price 3*s.* 6*d.*

PRODUCTIVE FARMING; or, a FAMILIAR DIGEST of the Recent DISCOVERIES of LIEBIG, DAVY, and other celebrated writers on VEGETABLE CHEMISTRY; showing how the results of English Tillage might be greatly augmented. By JOSEPH A. SMITH.

In small 8vo, price 5*s.*,

A SUMMER AT PORT PHILLIP; including the latest information regarding that Colony. By the Hon. R. DUNDAS MURRAY.

W. TAIT, Edinburgh; SIMPKIN, MARSHALL, and Co., London.

RELATION OF LANDLORD AND TENANT.

Just published, in one Volume, Royal Octavo, price two Guineas,

THE VALUE OF LANDED PROPERTY, demonstrated by practical Deductions and Illustrations, tending especially to facilitate the Valuation of Estates, as applicable to the purposes of Agriculture, in which is defined the Equitable Rent of the different descriptions of Land, and also the share of the Agricultural Products that constitutes the occupier's Profit. By LAYTON COOKE, Land Agent and Surveyor. Published by the Author, No. 7, John-street, Adelphi, London.

AGRICULTURE.—A Gentleman occupying a Farm of 600 acres, of various descriptions of soil, pleasantly situated in the highly cultivated county of Norfolk, and within five miles distance of three of its market Towns, is desirous of taking one or two YOUNG MEN, to learn the practice of Agriculture. The parties would in all respects be treated as members of the family, and would have the opportunity of regularly attending Norwich market (decidedly the largest and most celebrated provincial stock market in England,) and also the advantage of becoming acquainted with the most approved specimens of Agricultural Implements and Machinery. References given and required. Address, J. D., Post Office, Norwich.

FLORIST TO HER MAJESTY THE QUEEN.

WILLIAM MILLER, Florist, Nursery, Bayswater, Kent, begs to thank his numerous Customers and Friends for the great Patronage bestowed upon him last season, and at the same time to inform them that his List contains some of the greatest novelties ever offered to the Public, for which he solicits early orders, viz.:—FUCHSIAS, VERBENAS, PETUNIAS, &c., &c., for the Spring of 1844.

FUCHSIAS.

"Fuchsia Consolation.—This large and desirable variety was raised in the Providence Nursery, and is one of the finest ever produced. For description of this extra brilliant variety see Dr. Lindley's opinion, which will be found in the *Gardeners' Chronicle* of September 9th, page 633, under the signature, W. Miller. "Your hybrid, between fulgens and corymbiflora, is a very handsome flower, seed-pod small, tube long and slender, gradually increasing in size till the diameter is a quarter of an inch; the tube is a delicate pink colour, having sepals of a greenish principles, forming a strong contrast to the bright and red corolla seen between them; the flower altogether is 3½ inches in length, and the buds are very handsome as they approach maturity; it flowers in a large broad bunch, which is divided into branches, containing altogether 150 flowers."

It was also submitted to the Editor of the "Floricultural Cabinet," whose opinion will be found in Number 128, under the signature, W. M. "Your Fuchsia is a very fine one, and deserves cultivation in every situation." To be Figured in Spring.

Also noticed in the *Northern Times*, as the "Gem of 1844."

Plants to be had at 12s. 6d. each, with the usual allowance to the Trade, when not less than six Plants are ordered at one time.

[Except those marked thus*]

SPLENDID SEEDLING VERBENAS.

W. M. has two distinct and beautiful varieties to offer, feeling confident of their giving entire satisfaction. The one named "Lady Queen," has been submitted to Dr. Lindley, whose opinion will be found in the *Gardeners' Chronicle*, page 721, as follows:—"W. R., Your Sweet-scented Seedling, No. 105, is the best we have seen of its Colour—Bright Blue Lilac; the flower is large, smooth, and glossy, and perfectly free from crumple."—Plants in April, 5s. each, with the usual allowance to the Trade, when three or more are ordered at once.

The other, named "Zenens," is a beautiful rosy Vermillion, with large White Eye; this variety has also been submitted to Dr. Lindley, whose opinion will be found in the *Chronicle*, page 691.—"J. Miller, your Seedling named 'Zenens' is large and very brilliant.". Plants 2s. 6d. each, with the usual allowance to the Trade, when three or more are ordered at once. Figured, to appear in the *Florists' Journal*, for March.

W. M. can also supply all the new varieties of Fuchsias, Verbenas, Pelargoniums, Petunias, &c. &c. &c., to be sent out by other raisers at their advertised prices. Mixed Anagallis Plants for bedding, 4s. per doz. Also every article in the Trade at very low prices.

A few strong plants of his new Scarlet Geranium "Fireball," 5s. each.—allowance on three plants.

N.B.—Hybrid Pelargonium Seeds, saved from the very best sorts, 50 seeds, 5s.; 100 seeds, 10s. Fine hybrid Fuchsia Seed, 100 seeds, 7s. 6d.; 50 seeds, 4s. Fuchsia corymbiflora seed, 1s. per packet. Verbena Seed, from best varieties, 2s. 6d. per packet. Heartsease, from choicest named varieties, 2s. 6d. per packet. Carnation, from stage flowers, 2s. 6d. per packet. Calceolaria, from extra fine varieties (Shrubby and Herbaceous), 2s. 6d. per packet.—A remittance expected from unknown correspondents.

*** All Orders will be sent, packed in strong tin cases, Post-free where practicable to go by Post, or in pots by Coach and Railway, carriage paid to London.

Solicitors.—Messrs. Blanchard, Richardson, and Gutch, York.
Draining Engineer.—James Smith, Esq. (Deanston).
Secretary.—John H. Charnock, Esq., Wakefield.

This Association is formed for the purpose of affording to the Agricultural Interest, by means of its collective capital, the funds necessary for the *thorough Draining of Land:* and of executing and superintending the execution of the works required for this purpose on the most economical and effective principles; repayment of the money advanced to be made, with interest, by such equitable half-yearly instalments, as in the several cases may be determined.

Among the various objects to which of late years collective capital has been more or less successfully applied, it is not a little surprising that the one which, of all others, offers the most certain and profitable return, with the soundest security, should have hitherto been almost disregarded. The time, however, has arrived, when an urgent desire for Agricultural improvement on the one hand, and a dearth of safe and profitable investment for superabundant capital on the other, renders such an Association highly desirable to both the Landed and Monied Interest, whilst to the community generally an almost incalculable advantage will be secured by a proportionate increase of labour and food.

The Principles upon which such an application of Capital may be securely based, have been already recognised by the Legislature in the Act of 3d and 4th Victoria, cap. 55, passed for the purpose of enabling the owners of settled estates to defray the expense of draining the same by way of mortgage, and to charge all or any part of the lands so drained, or other lands held therewith, with the payment, to any person or persons willing to advance the same, of the amount of the money which may have been expended, together with interest thereon, by equal yearly instalments of not less than twelve, nor more than eighteen; such instalments to be diminished or increased according to the greater or less improvement shown to have been made by such draining. Or the parties may charge the said lands with a rent-charge for any such period as aforesaid. The Preamble of this Act expresses so clearly the objects of this Association, and at the same time shows the importance attached by the Legislature to the subject, that it is here extracted:—"Whereas much of the land in England and Ireland would be rendered permanently more productive by improved draining, and nevertheless, by reason of the great expense thereof, Proprietors having a limited interest in such land are often unable to execute such draining; and whereas it is expedient, as well for the more abundant production of food, for the increased employment of Farming Labourers, and the extended investment of Capital in the permanent improvement of the soil, that such Proprietors should be relieved from the disability, due regard being had to the interests of those entitled in remainder."

The object of the present undertaking is to avail itself of the provisions of this Act, so far as they apply, and by offering an ample and easily-accessible capital, to induce the parties contemplated therein to seek the benefit of its provisions; and, at the same time to afford to the Agricultural Interest generally, on equitable terms, and on the same principle as that on which the act proceeds, the requisite means for thoroughly draining their land.

The Capital to be 500,000*l.*, in stock of 25*l.*, with a deposit of 5 per cent. on its allotment; the amount and time of the calls to be regulated by the demand, as it arises, for the beneficial employment of the money, and so that no one call exceeds 10 per cent., with a notice of not less than two months for each payment.

The management to be under an effective Committee, elected by and from the Subscribers, with the most efficient Staff that can be selected for practical and scientific skill in their several departments.

The head office to be in York, with Agencies in other towns of the county and elsewhere, as the demand for the assistance of the Association may require, and as it may be found advantageous to extend the sphere of its action.

The Meetings of the Committee of Management to be held Monthly, or oftener if necessary, and of the General Subscribers Annually, to receive the Report of the Committee, pass the Accounts, and transact other general business.

Interest after such a rate as the Committee of Management may see reason to recommend, to be allowed half-yearly on the Capital paid up, so soon as the returns on the money expended will permit; together with such further division of profits as, on a General Settlement to be made every four years, the affairs of the Undertaking will justify.

The Accounts to be balanced annually, prior to the General Meeting, and audited by competent parties duly elected.

The Association will, if thought necessary, apply for Letters Patent, and also for an Act of Incorporation, should it be subsequently found expedient to do so, in obtaining which it is probable no impediment will arise.

Viewing the prospects of the Farming Interest with reference to the effect which may result from the late or any future relaxation of the protective duties on Agricultural produce, and considering that the issue must, in some degree, be experimental, the position of the Agricultural Community seems emphatically to call for the most active promotion of every practical improvement, which, by securing an increase of production, may tend to counterbalance the depression consequent upon any reduction in prices. That the operation of this Association will greatly contribute to this end, can scarcely be questioned, one common interest inducing both Owners and Occupiers to avail themselves of the means thus offered; securing to the former the permanent improvement of their estates, and to the latter an immediate return considerably exceeding any charge which the cost of the works may for a time entail. Great advantage will be also secured in having the draining performed under the direction of the Association, which, in order to guarantee the most effective execution of the works, will in all cases avail itself of the first practical and scientific talent.

With reference to the security to be taken for advances made by the Association, it is of the utmost importance both to the undertaking and also to those who seek its assistance, that they should be effected at the least possible expense which prudence will justify. There is little doubt but that an Act of Parliament will be passed in the ensuing Session, amending the present Drainage Act, and affording increased facilities to all parties interested in the subject, by means of which it is expected a very concise yet effective charge may be created at a moderate expense. In the meantime, the Association will, in the case of settled estates, deal entirely with the Landlord, and under the protection afforded by the present Drainage Act. In other cases the Association proposes to take a simple charge on the Estate or the Bond, or joint Promissory Note of the person draining with one or more sufficient sureties, and in all instances where practicable to have the Owner a party whose interest it will be to co-operate with his Tenant in placing the Association in a secure position. And in those districts where the system of *full valuation* prevails, safety will be doubly ensured, from the practice of valuing the residuary proportion of the cost to the on-coming party.

At a meeting of the Council of the YORKSHIRE AGRICULTURAL SOCIETY, held in York on the 20th of December, 1843, a resolution was passed approving generally of the objects of this Association; and at the monthly meeting of the Wakefield Farmers' Club, held on Jan 5, 1844, a resolution approving of the principle and objects of the Association was unanimously adopted.

At the meeting of the Royal Agricultural Society of England, at Liverpool in July, 1841, Lord Stanley remarked that, "There was no bank in the whole country—no commercial speculation—no investment so safe, so pure and profitable, as that in which even borrowed capital may be engaged, by investing it under the ground of your own soil." And in reference to this Association, his Lordship in a letter to the Committee says—"I am fully satisfied of the benefits which such an Association is capable of conferring on the country if confined to its legitimate object—the lending of Capital on the security of an investment in draining; and I think it very probable that many Landed Proprietors would avail themselves of the facilities afforded by an institution lending money on land, repayable by instalments—a condition, on which few private parties are willing to lend."

Bearing in mind, then, the important objects of the Association, and the perfect security with which its operations can be conducted, at a comparatively trifling expense (no large expenditure for previous outfit being required), it may be reasonably expected that the return of the Capital embarked will be such as to insure the support of prudent and *permanent* Investors, thereby divesting it of that speculative character which has stigmatised so many modern projects, and which it is the especial desire of the Committee to avoid.

Applications for Prospectuses, &c., to be addressed to the Solicitors, Messrs. Blanchard, Richardson, and Gutch, York; or, to J. H. Charnock, Esq., the Secretary, Wakefield.

Printed by Messrs. Shaporry and Evans, Bouverie-street, Fleet-street in the Precinct of Whitefriars, in the City of London, and Published by them at the Gardeners' Chronicle Office, Covent Garden, in the County of Middlesex, where all Advertisements and Communications are to be addressed to the Editor.—Saturday, February 17, 1844.

IPSWICH HORTICULTURAL AGENCY OFFICE for the sale of NEW AND RARE SEEDS, &c. &c.

LATTER'S VICTORY OF ENGLAND is sold out. The raiser will use the best means of preserving the pure Stock of this celebrated Cucumber.

HAMILTON'S TREATISE ON THE CULTURE OF PINES, GRAPES, and CUCUMBERS, in the same House, by which system the Cucumbers will pay all the expenses of growing, (in addition to a crop of grapes,) 300 lbs. of splendid Pine-apples annually from the same Plants. T. Wild is promised the first supply, and hopes to have the pleasure of forwarding a copy, postage free, to Subscribers, on Tuesday next; this unexpected delay is entirely the printer's fault. 6s. per copy.

West India Giant PEA—very prolific; and although the size and shape of Tick Beans, most delicious flavour: 1s. 6d. a quart.

RENDLE'S TANK SYSTEM OF COMMUNICATING BOTTOM-HEAT, 2s. 6d. per copy.

A few first-rate Scarlet and Green MELON SEEDS, 1s. per packet. A very small quantity of Latter's unrivalled Coxcomb, Balsam, and Germ. ASTER SEED, 6d. per packet.

On receipt of post-office order for any of the above, they will be forwarded immediately, free of postage. An extra quantity of Peas will be enclosed to pay carriage.—Thomas Wild, 3, Tavern Street, Ipswich.

GENUINE BEECHWOOD MELON SEED.

R. GLENDINNING respectfully begs to inform the Cultivators of the MELON that he has had presented to him by Sir John G. Shelley, Bart., Seeds of the *true* variety of this delicious MELON; for besides being one of the very best sorts known, it is of easy cultivation and a good bearer. This opportunity will enable Gentlemen to procure it *quite genuine*, which is rarely the case, as the following note will testify:—

"Beechwood, Feb. 5, 1844.

"Sir,—I send you a small parcel of the Beechwood Melon Seed. None that I have seen exhibited under that name, nor any that I have seen grown from Seed that has been bought, are of the true sort, but have obviously been intermixed with other varieties. I have grown no other for many years.

"Your obedient servant,

"To Mr. Glendinning. J. S. Sebright."

R. G. has also a few Seeds of the true SION FREE-BEARING CUCUMBER, a splendid variety which has been nearly lost.

Packets of the above sent by post free.

Beechwood Melon per packet . . . . 5s.

Sion Free-bearing Cucumber, per packet . 5s.

R. G.'s Kitchen-garden and Flower-seeds have been selected with great care, and embrace all the new and good kinds.

Chiswick Nursery, near London, Feb. 16, 1844.

JOHN HANCOCK and SON, Nurserymen, Durham, beg to direct attention to their Advertisement of FUCHSIA LOWRYII, NEW FUCHSIAS, GERANIUMS, &c., inserted in last week's *Chronicle*.

Fuchsias.—Fine strong healthy plants of the following will be ready by the 1st of March, and can be sent by Post at 20s. per dozen, if the Plants are not required to be too large:—Brockmanii, Ballooniflora, Cormackii, Champion (Smith's), Britannia (Smith's), Defiance (Smith's), Exoniensis, Eppsii, Dennisiana, Fairy Queen, Gem (Ivery's), Iveryana, Lanell, majestica multiflora (Knight's), multiflora coccinea (Knight's), majestica (Smith's), nobilissima (Smith's), Paragon (Smith's), Rogersiana, St. Clare, Stanwelliana, Swalesii, and Toddiana.

General Descriptive Catalogues of Plants may be had on application, by sending two postage stamps.—Wear Nurseries, Durham.

NEW AND SUPERB FUCHSIAS, VERBENAS, PETUNIAS, CINERARIAS, and other Plants adapted for Bedding.

WM. WOOD and SON, of Maresfield, have the pleasure to apprise their numerous Friends that a Catalogue of the above, including a Supplementary List of New and Choice Greenhouse and Herbaceous Plants, Camellias, &c. &c. is now in course of preparation, and may be had Gratis on application in March, and which will be found to contain every new and desirable variety. A Select List of entirely new and superb Roses will be added.

W. W. & Son will undertake to supply orders to any extent for the above-named collection of Plants, to be sent out early in May.

N.B.—Agents by appointment for Warrner's Chemical Transparent Waterproof Composition, sold in bottles, with directions for use—Pints, 2s. 6d., Quarts, 4s. 6d. each.

Woodlands Nursery, Maresfield, near Uckfield, Sussex.

JOHN CATTELL, Seed and Nurseryman, Westerham, Kent, begs to call the attention of the Public to his Superior Stock of Seeds, Trees, and Plants, separate Catalogues of which are now ready. Standard and Dwarf ROSES remarkably fine. Bedded plants of the newest and best sorts of Strawberries. A good stock of the New Improved Autumn Raspberry, "Rodger's Victoria," warranted true at 3s. 6d. per dozen, 25s. per 100. A few good plants of Veronica speciosa. Seeds carefully packed for exportation.

J. C. is in want of a few hundreds of seedling Azalea pontica, single stemmed plants, about the size of a common pen-quill, a plant or two of which, as sample, may be forwarded, with price and quantity per Post.

CROSS-LANES NURSERY, near BEDALE, YORKSHIRE.

W. JACKSON and Co., in returning their sincere thanks to the Nobility, Gentry, and Public for their liberal patronage, beg to announce that they can still supply the following of first-rate quality, which will be forwarded with the utmost despatch to any part of the kingdom. Delivery at the railway gratis.

100 select showy Herbaceous Plants, in 50 named sorts, for 25s.
100 Dwarf Roses, in 50 named sorts, for 20s.
100 Do. in 100 named, very fine sorts, for 50s
100 Do. in 100 do., extra fine sorts for 75s.
50 Standard Roses, in 50 splendid varieties, including the fine Hybrid Perpetuals, for 80s.

A Large Stock of fine transplanted English Oaks of all sizes.

Catalogues may be had on application, inclosing two postage stamps. A remittance or reference from unknown correspondents is respectfully solicited.—Feb. 20th, 1844.

FASTOLFF RASPBERRY.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, THE MOST NOBLE THE MARQUIS OF AILSA, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL and Co. have much pleasure in announcing they are now supplying fine Canes of the above highly-valuable and much-esteemed RASPBERRY, unequalled for the extraordinary size of its fruit and richness of flavour.

Those to whom Y. and Co. sent it last season have expressed their high admiration of its superiority over all other varieties, and has been awarded several prizes at various Horticultural exhibitions during the season. As a proof they have not exaggerated its excellent qualities, fruit was submitted to Dr. Lindley, (see *Gardeners' Chronicle* of the 22d July last, page 502), whose opinion of it is as follows:—

"Fastolff Raspberry.—We have received from Messrs. Youell, of Great Yarmouth, fruit of the Fastolff Raspberry, and we find it merits all that has been stated in favour of its excellence. The fruit that we have received is very large, obtusely conical, and of rich flavour, far exceeding in this respect some other new and large varieties. The plants bear abundantly and in long succession."

They also exhibited it on the 1st of August, 1843, before the London Horticultural Society, 21, Regent-street, to which a prize was awarded. It would therefore be unnecessary for Youell and Co. to recommend it more fully, or with greater confidence, to the notice of the public, merely observing, that it continues in high perfection throughout the autumnal months, and has maintained its superiority in the most unfavourable soils and situations, and requires no other than the ordinary treatment of the old varieties.

Fine Canes are ready for delivery, and can be sent with safety to any part of the United Kingdom (on the receipt of a Post-office order), upon the following terms:—

Packages containing 100 Canes		£2	5s. 0d.
Do.	do. 50 do.	1	5 0
Do.	do. 25 do.	0	14 0

Package included.

The usual discount to the Trade, when not less than 200 are ordered.

*** Caution.—Y. and Co. beg to call the attention of their Friends and the Public in general to the fact that they have appointed no Agents in London for the sale of the above, and cannot be held responsible for its being genuine unless purchased direct from their Nursery.

YOUELL'S TOBOLSK RHUBARB, Patronised by Her Most Gracious Majesty the Queen, and many of the Nobility, 12s. per dozen. For particulars of which see their Advertisement of the 18th November.

TWO NEW SEEDLING PICOTEES.—"Lady Alice Peel," 10s. 6d., and "Mrs. Benyon," 10s. 6d. per pair.—These two splendid Picotees were raised by the Rev. J. Burroughes, of Lingwood Lodge, Norfolk, and kindly presented by that gentleman to Messrs. Youell and Co., for particulars of which see their Advertisement in this Paper of the 16th of Sept.

FINEST CARNATIONS and PICOTEES.

YOUELL and Co. beg to refer the readers of the *Gardeners' Chronicle* to their Extensive List, with Prices, of the above highly-esteemed Flowers, which appeared on the Advertising pages, 706 and 707, of this Paper, of October the 14th, and will be found to contain every variety worthy of cultivation.

Prices as follows:—

		£	s.	d.
12 pair of good Show Sorts		1	4	0
12 ditto fine	ditto	1	10	0
25 ditto	ditto	2	0	0
12 ditto extra fine and very superior	ditto	2	10	0
25 ditto	ditto	5	0	0

The selection being left to Youell and Co.

ARAUCARIA IMBRICATA.

YOUELL and CO., possessing the most extensive stock in the country of the above Splendid Hardy Ornamental Tree, beg to offer them on the following advantageous terms:—Fine robust 4-year-old plants, 6 to 12 inches high, 16s. per 100, or 30s. per dozen.

Fine Plants of CEDRUS DEODARA, 2ft. to 2ft. 6 ins., 10s. 6d. each.

Great Yarmouth Nursery, Feb. 22, 1844.

RANUNCULUSES.—The season for planting this beautiful Flower having arrived, MESSRS. TYSO & SON, Wallingford, respectfully announce that they can supply from their collection of *Seven Hundred Varieties*, strong roots of most of *the leading Show-flowers*. Priced Catalogues will be sent prepaid to applicants forwarding two Postage labels.

DAHLIAS.

J. KEYNES, Florist, Salisbury.—"Standard of Perfection." (Keynes).—The finest self-coloured Dahlia in the world! gained the 1st class prizes at Stonehenge, Windsor, Kingston, Surrey Zoological Gardens, and Crown and Anchor, Stockwell; also the 1st prize specimens at Stonehenge Floricultural Society, Stockwell. "It is as round as any Dahlia in cultivation; as complete an unbroken circle as could be drawn with the compasses; and as globular in front as possible. It is symmetrical to a hair, and as double as a Ranunculus. It is so remarkable as to be instantly recognised among a thousand. Colour, deep crimson. It is the flower of the season, and must be had."—*Gardeners' Gazette*, Oct. 14. "The best-grown flower we ever saw, without exception, every requisite to meet the taste of a connoisseur being complied with; good colour, a handy-comb, regularity of growth and disposition in the leaves, and above all, as complete a rotundity of shape as if it had been cast in a mould."—*Salisbury Herald*, Sept. 2, 1843. Plants in May, 1844, 10s. 6d. "Orange Superb," (Dodd's) first-rate show-flower, 10s. 6d. "The specimen sent would grace any stand."—Glenny. "Emma Noke," (Dowding's) bluish white, extra fine, indispensable to a first-rate stand, 10s. 6d. Catalogues containing all the fine old varieties and new flowers for the season may be had on application.—Salisbury, Jan. 31, 1844.

LARCHES, transplanted of Sizes, are still on Sale at very low prices, by Wm. Urquhart & Sons, Dundee.

WILLIAM MASTERS begs to call the attention of the Nobility, Gentry, &c., to his newly and well-assorted COLLECTION OF GARDEN AND FLOWER SEEDS, which, being principally grown under his immediate inspection, he can particularly recommend.

100 papers finest Annual Flower Seeds		£1	1s. 0d.
50	do. do.	12	6
25	do. do.	6	6

[If the selection is left to W. M.]

Forwarded by Post without additional charge.—POTTER'S ARTIFICIAL GUANO and CONCENTRATED LIQUID GUANO.

Exotic Nursery, Canterbury, Feb. 1844.

NEW AND SUPERB COLLECTION OF SEEDLING FUCHSIAS.

W. J. EPPS begs to announce that he purposes sending out, on the first week in March, Ten Magnificent Seedling Fuchsias, which have merited high opinions from the most distinguished judges of the day. They are very distinct, and possess the finest properties of any Fuchsias yet known.

BRIDEGROOM (Epps').—A fine flower, of great size and splendour, light pink tube, sepals very smooth and rich, beautifully tipped with green, corolla very large, of a deep vermilion colour, very like Chandleri, but twice the size; of a splendid erect habit, and a very free bloomer.—(This was submitted to the Editor of the *Florist's Journal* in November last. See Answers to Correspondents.) Price 5s.

ESPARTERO (Epps').—This flower is of large size, tube long, bright scarlet, short sepals, expanding well, and exhibiting an extraordinary large deep rich rosy-purple corolla, immense bloomer, and a very distinct variety.—(See Mr. Ayres' opinion, *Gardeners' Chronicle, Nov. 25, 1843*, on the article of Fuchsias). Price 7s. 6d.

KENTISH HERO.—*A fine flower*, of a beautiful vermilion red tube, and sepals well expanded, exhibiting a splendid pure-purple corolla of great substance, very distinct; fine compact habit. Price 5s.

DUKE OF WELLINGTON.—*An immense flower*, of great substance, very rich rosy pink tube, and sepals beautifully smooth and slightly tipped with green, very large corolla, of a rich rosy crimson, sepals expand well, almost reflex; fine free habit. Price 5s.

WINSERII.—(Professor Lindley's opinion, see *Gardeners' Chronicle, Aug. 5, 1843*, to Correspondent, *J. W., Tenterden.*) Price 5s.

"No. 1, tube long and smooth, of a rosy crimson, sepals open very wide, with the points slightly tipped with green, corolla short, of a rosy vermilion colour; *a fine variety.*"—Professor Lindley.

MARIA.—"No. 3, tube and sepals rose-coloured and smooth, corolla large, of a fine bright blue purple; *an elegant variety.*"—Professor Lindley. Price 5s.

FLORENCE.—"No. 6, tube smooth, sepals spreading, rosy in colour, with the points slightly tipped with green, corolla rosy-purple; *very pretty flower.*"—Professor Lindley. Price 5s.

"All these seedlings are good in form, bright in colour, and smooth in texture."—Professor Lindley.

KENTISH BRIDE.—This magnificent flower was raised by H. Busby, gardener to T. L. Hodges, Esq., Hemsted, Kent, and has merited the high opinion of Professor Lindley, Editor of the *Gardeners' Chronicle*; Mr. G. Glenny, Editor of the *Gardeners' Gazette*; and Mr. Ayres, the able writer on the Amateur's Garden. Price 7s. 6d.

Professor Lindley's opinion, see *Gardeners' Chron.*, July, 8, 1843, to correspondent, *H. B.*—"Your best Seedling Fuchsia is No. 4. This is a beautiful variety, seed-vessels bright green, tube and sepals bright rosy scarlet, corolla large, of a bright violet-purple. It is a well-proportioned flower."

Mr. Ayres' opinion, see *Gardeners' Chronicle*, Nov. 25, 1843.

Mr. G. Glenny's opinion, see *Gardeners' Gazette*, Oct. 21, 1843, to correspondent, *W. J. E.—Fuchsia*,—"Pink sepals, rich purple corolla, long footstalk. If the habit of the plant be as good as the flower, it is an acquisition."

The habit of this plant is very compact, and of a beautiful rich green glossy foliage, and with its rich pink tube, sepals, and blue purple velvet corolla, forms a lovely object.

EMPEROR OF CHINA.—This is a fine flower raised by the same person as Kentish Bride, and submitted to Professor Lindley at the same time. Price 5s. "No 1, which is similar to No. 2, and having a stout tube. This is a fine flower, with less blue in the corolla."—Professor Lindley.

PRINCE OF WALES.—This also was raised by H. Busby, and submitted to Professor Lindley with two others. *An immense Bloomer.* Price 5s. "No. 3 is a stout flower of a good colour, with long sepals, which expand freely and expose the corolla, which is of a rosy purple."—Professor Lindley.

*** The Collection, Two Guineas and a half. A remittance from unknown Correspondents. The usual allowance to the Trade where two or more plants are taken.—Bowes Nursery, Maidstone, Feb. 22, 1844.

SEED TRADE.—NO MONOPOLY!

J. G. WAITE, in returning thanks for the very liberal support he has received from the Country Trade, begs to assure them that the report so freely circulated by the London Seedsmen as to his being unacquainted with the Seed business is untrue, he having been engaged therein for 14 years as grower and dealer, although he never solicited country orders until this season.

J. G. W. begs to submit a Catalogue of Seeds, &c., which are of first-rate quality; and all orders shall have careful and immediate attention:—

	s.	d.
Waite's Queen of Dwarf Peas . per quart	2	0
[A splendid new variety, growing only one foot high, producing a larger pod than any of the same habit; the seed is quite distinct from all others, and larger than any dwarf Pea in cultivation. The stock is limited to a few quarts.]

J. G. W. has lately received a large freight of very superior Ribbon Onion, which he offers at 1s. 10d. per lb. Samples may be had by sending a letter inclosing two postage stamps, which will allow purchasers an opportunity of proving the stock before it is wanted for autumn sowing.

J. G. WAITE'S priced Catalogue of Flower Seeds is now ready, and may be had on application at his Establishments, Nos. 1 & 4, Eyre-street-hill, Hatton-garden, London.

N.B. A remittance or reference in London is required previous to opening an account.

R. WHITE & Co.'s Collection of Plants, of which a Catalogue is now ready, comprise every variety of Geranium, Fuchsia, Verbena, Chrysanthemum, Dahlia, &c. which is worthy of cultivation. The following collections are offered, the selection being left to the purchaser:—

			£	s.	d.
40 first-rate varieties of	Geranium	. . .	5	0	0
20 ,, ,,	do.	. . .	3	0	0
12 ,, ,,	New do.	. . .	2	0	0
20 ,, ,,	Fuchsia .	. . .	1	1	0
40 ,, ,,	Chrysanthemum	. .	1	1	0
20 ,, ,,	Verbena, including Seedlings which were submitted to Dr. Lindley for his opinion, and reported to be "all very fine," see *Gardeners' Chronicle*, Sept. 30th and Oct. 7th: "*Alfred*; All your Seedling Verbenas are good flowers."	. . .	1	1	0
12 first-rate Dahlias		. . .	1	1	0
100 fine show do.		. . .	3	10	0

The above will be ready for delivery in strong plants the first weeks of April and May; and orders containing remittances will be executed in strict priority. Orders amounting to 5l. will be delivered free.

Agents for the sale of STEPHENSON'S Conical Boiler, Tank, &c., which may be seen at work, and can be supplied at Manufacturers' prices. Also WHITNEY'S Composition Substitute for Glass.—Poole Nursery.

FLOWER SEEDS—36 Packets, 10s.; 18 ditto 5s., forwarded, postage free, to any part.—Apply to Mr. JOHN BROWN, Albion Nursery, Stoke Newington, London. Any preferred species may be specified in the order. Payment by Post-office order or stamps.

J. H. B. has on sale an extensive collection of the most approved Plants for greenhouses and conservatories. Parties building large or small greenhouses can be well supplied.

HURST & M'MULLEN, SEEDSMEN and FLORISTS, 6, Leadenhall-street, beg respectfully at the present season to invite the attention of the public to their extensive and well-selected Stock of GARDEN SEEDS, comprising every new and choice variety worthy of cultivation. They annex the names of a few varieties deserving particular notice, for present use, and beg to say their List of NEW AND CHOICE FLOWER-SEEDS, of which they possess an unrivalled collection, will appear at the usual time in "Harrison's Floricultural Cabinet" for March, and in the *Gardeners' Chronicle* of the 2d March.

HURST and M'MULLEN beg to thank their Friends for the kind and encouraging patronage they have received, and to assure them that all commands shall have careful and prompt attention.—Wholesale and Retail Seed Establishment, 6, Leadenhall-street; Warehouse, 15, Vine-street, Minories.

LAWN GRASS SEED.—Mixtures of the finest kinds of GRASSES and CLOVER, warranted to produce a fine Sward (allowing two quarts to the square rod), 14s. per bushel. Seat carriage paid to London, in not less quantity than half a bushel. Mixtures for Lawns intended to be fed, 10s. per bushel.
JOHN RIVERS, Sawbridgeworth, Herts.

BUSHELL'S Light Seedling Dahlia "EMMA."—Plants in May, 10s. 6d. Colour white, tipped with deep cherry; the petals, form, and centre, good; the largest, most constant, and free in flowering of any Dahlia yet propagated, and has obtained several prizes. "Pet Rival" Plants in May, 5s. Colour, purple maroon; fine cupped petal and free bloomer; exhibited in several winning stands last season. Kennington Rose, Plants in May, 5s.; most constant Rose grown. To be had of Messrs. ANGELL, Camden Town; B. GIBLING, Bloomsbury; F. and A. SMITH, Hackney; and J. BUSHELL, 12, Hall-place, Kennington-lane.

NEW SEEDLING FUCHSIA "SIDMOUTHII" will be ready to send out in May next; price 10s. 6d. each, carriage free.—This magnificent variety was raised last year by Mr. BARTLETT, Nurseryman, Sidmouth. It may be considered the finest hybrid extant. The flowers are large and colour brilliant, is a strong grower and prolific bloomer, with fine foliage. A specimen flower was sent to the Editor of the *Gardeners' Chronicle* last October, who spoke so high in its praise that anything further is superfluous, beyond its character as above. Visitors to Sidmouth will be gratified by viewing Mr. B.'s Collection of this lovely and graceful flower; having a mode of treatment peculiarly his own.

*** To secure fine plants early orders are desirable.

RANUNCULUSES, ANEMONES, CARNATIONS, AURICULAS and LILIUM LANCIFOLIUM.

H. GROOM, Clapham-rise, near London (removed from Walworth), by appointment FLORIST TO HER MAJESTY, begs to remind the Nobility, Gentry, and Amateurs, that this is the best season for obtaining Collections of the above Flowers, and that in consequence of the success he had in their cultivation last year, he can offer them at the following moderate prices:—

,, ,, ,, large bulbs, each . .	0	10	6
,, ,, punctatum, good bulbs, each	0	7	6
,, ,, ,, large bulbs, each	1	1	0

Catalogues may be had on application.—Feb., 1844.

ORANGE AND LEMON TREES, from 8s. to 25s. DOUBLE ITALIAN TUBEROSE ROOTS, 3s. per dozen.—R. HALL begs to advise the arrival of his Annual Importation of the above-named Trees and Bulbs, which are this year remarkably fine, at his Foreign Warehouse, 63, South Audley-street, Grosvenor-square—facing the Chapel.

TO GENTLEMEN PLANTING.

J. AND J. FAIRBAIRN are induced from the uncertainty upon which they hold the Manor-street Nursery (situated contiguous to the Home Nursery, Clapham Rise, where attention will be given to all applications), to effect a Sale of the Stock at as early a period as possible, consequently beg to solicit the attention of Gentlemen and the trade to the large and remarkably healthy and well-grown stock, consisting of fine large Laurels, twice transplanted, of extra growth; Portugal Laurels, very handsome; Green Hollies, of various sizes; Evergreen Privets, fine Standard and Dwarf Roses in great variety, fine standard flowering Thorns, Almonds, Æsculus, Robinias, and other Ornamental Trees, and Evergreen and flowering Shrubs, with a large stock of fine standard and dwarf, trained and untrained Peaches, Nectarines, Apples, Pears, Plums, and Cherries, of the most approved kinds, and of growth rarely equalled; also, a large assortment of Forest Trees, consisting of Limes, Elms, Birch, Beech, Hornbeam, Spanish and Horse Chesnuts, Mountain Ash, Poplars, and Spruce, and Scotch Firs; also a large number of Gooseberries and Currants, of excellent growth, and of the best varieties in cultivation, to all of which J. & J. F. respectfully invite the inspection of Gentlemen and Nurserymen, flattering themselves that the general character of the Stock is such as to ensure unqualified satisfaction, and which they are disposed to offer at very moderate prices for cash.

J. & J. F. respectfully beg to call the attention of Gentlemen to their advertisement of Heaths, &c., which appeared in the *Gardeners' Chronicle*, Oct. 21 and 28.

Nurseries, Clapham, near London, Feb. 16, 1844.

THE BRITISH QUEEN AND PRINCE ALBERT PEAS.

WM. JNO. CORMACK begs to call the attention of Noblemen, Gentlemen, and others, to the above two new Varieties, the merits of which are thus noticed in the *Gardeners' Chronicle*. "THE BRITISH QUEEN on light soils, is the best of all kinds, and will drive Knight's Tall Marrow out of the garden." "THE PRINCE ALBERT, which has been cultivated in the Garden of the Horticultural Society during the season, produced Peas fit for the table *ten days earlier* than any other variety sown at the same time." Both varieties may be had in packages at 3s. 6d. each, at W. J. C.'s wholesale Establishment, Newcross, or the Bedford Conservatory, Covent Garden.

THE KENSINGTON NURSERIES.

THE LEASE of one of these Nurseries expires shortly, and the Ground being required for building purposes, Messrs. PROTHEROE AND MORRIS are instructed to offer to public competition the invaluable Stock on the smallest of these Nurseries, in the occupation of Messrs. FORREST and Co., and the Stock being far superior to any within a considerable distance, will afford Gentlemen, Noblemen, and others engaged in planting, a fine opportunity to supply themselves, not likely soon to recur. The sale is on the 4th March, and following days, and includes ornamental Trees and Shrubs of every description, variegated and Green Hollies, Evergreen Oaks, and Cork Trees, large Fan and other Yews, twice transplanted Common and Portugal Laurels, Arbutus alaternus, Hemlock, Spruce, &c. May be viewed prior to sale. Catalogues 1s. each, returnable to purchasers, may be had on the premises, of the principal Seedsmen, and of the Auctioneers.—American Nursery, Leytonstone.

TO AMATEUR FLORISTS.

TO LET, at a low Rent, a SMALL HOUSE, with a VERY LARGE GARDEN, Greenhouse, and Pit. Inquire at No. 1, Mapp's Row, Stepney Green.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE & MORRIS will submit to Public Competition at the Auction Mart, Bartholomew-lane, on THURSDAY, Feb. 29, 1844, and following day, at 12 o'Clock, about 200 DOUBLE CAMELLIAS, consisting of all the leading varieties, beautifully furnished with bloom-buds; also a fine assortment of STANDARD and DWARF ROSES, AMERICAN PLANTS, DAHLIAS in dry roots, &c. May be viewed the morning of Sale. Catalogues may be had at the Mart, and of the Auctioneers, American Nursery, Leytonstone.

*** The Camellias will be sold on Thursday, 29th.

THE NEWEST AND VERY BEST FUCHSIAS, VERBENAS, PETUNIAS, ANAGALLIS, &c.
FOR 1844.

YOUELL AND CO. beg to refer the Readers of the *Gardener's Chronicle* to their Catalogue of the above, which appeared in this paper of last week, and will be found to contain such varieties only as are worthy of cultivation.—Great Yarmouth Nursery, Feb. 22, 1844.

WILLIAM MASTERS begs most respectfully to inform the Nobility and Gentry of the United Kingdom that he unites the Professions of LANDSCAPE-GARDENER and NURSERYMAN, and this enables him to offer an extensive Collection of Coniferæ Plant, as well as of the Hardy Ornamental Trees and Shrubs cultivated in Britain, at very moderate prices. W. M. also possesses a numerous Assortment of Hothouse and Greenhouse Plants, many of the rarer species of Orchidaceæ, several new hybrid Crinums, Rhododendrons, Azalea indica, Camellias, Succulents, Pelargoniums, &c. &c.—Exotic Nursery, Canterbury, Feb., 1844.

CHEAPER THAN EVER!

W. MILLER begs to inform his numerous Friends that he offers the following Beautiful Plants cheaper than last season, viz.,

12 Fine new distinct Fuchsias for .....7s. 6d.
12 Splendid Verbenas 3 6
12 Anagallis, fine sort.....4 0
Petunia Punctata, per Plant 7 6

See Mr. M.'s extensive List in last week's *Chronicle*, containing every new variety.—Providence Nursery, Ramsgate.

The Gardeners' Chronicle.

SATURDAY, FEBRUARY 24, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Wednesday, Feb. 28	Society of Arts	. .	8 P.M.
Friday, March 1	Botanical	. .	3 P.M.
Monday, March 4	Entomological	. .	8 P.M.
Tuesday, March 5	Horticultural	. .	3 P.M.
	Linnean	. .	8 P.M.

In pursuing the subject of LANDSCAPE GARDENING, and attempting in a plain manner to make principles easily understood, we cannot too often repeat that we must look to Nature as our instructress. Not only, however, must we look to external, but to internal nature; that is, into our own mental constitution. It may not have occurred to some, that science, as well as art, is necessary to the exercise of Landscape-Gardening; and few, probably, have imagined that geology can aid us in tracing to their origin the most sublime spectacles which Nature presents to our view. A brief appeal to that science will not appear either uninteresting or useless.

Very little observation and inquiry is needed to satisfy us that the abode of man, this fair world, was made in all respects fit for his residence before he was called into existence. Geologists have observed the effects of the various revolutions which this globe has undergone—that destruction and renewal have been never-ceasing operations—that they are the very basis of creative design; and, when investigated, they appear to be the sources of all our enjoyment—startling as to some the remark may seem. We are taught by geology that what are called strata and rock were all originally deposited in conformity with the curvature of the earth. These have, at different periods, been invaded and broken up by rocky matter in a state of fusion; and finally, it appears, from the extremely disturbed state of the entire crust of the globe, and the elevation of igneous rocks, that a tremendous force acting from below upwards has dislocated the whole, so that immense masses have been erected into the forms of mountains and hills, while others have sunk into the abysses left by the escape of the expansive fluid, which was most probably steam. The bottom of the ocean is as uneven as the surface of the earth; and islands and volcanoes testify what has been done, and by what agency.

Here, then, we find destruction to be the origin of all that is admirable in Landscape, so far as the unevenness of the surface is concerned. To this destruction we owe the stupendous, ragged, and snow-capped mountain, the overhanging precipice, the lake, the valley, and the river. The elevation of the land causes water to flow, and its disturbance has caused the necessity for its being precipitated in the form of falls and cascades, producing many of the most sublime and beautiful spectacles which Nature offers to our contemplation.

It is, indeed, at first view, a strange coalition; nevertheless, without destruction, there could be neither sublimity nor beauty. The association is unavoidable, and fatal to the ideal theory of Taste. To sublimity and beauty destruction has been, and is still, and will be while the world lasts, the servant of all-work; for we find it above us, in the thunder—beneath us, in the earthquake: on every side, in the tempestuous wind, and in the raging billows. Nor do we find it alone in the terrible of Nature's powers. In our quiet and peaceful domestic concerns destruction steers his unregarded course. The hand of the artisan is for ever at work, destroying a part of his materials to render the remainder useful or ornamental. The powers of fire and of water are called upon to clothe us. Destruction gives us food and light; and from the rough block of stone fashions the statue and the temple. Wonderful! that the faculties of man should have been created to derive enjoyment from the effects of what he dreads and shrinks from! To him an All-wise Intelligence has extended blessings which unlimited benevolence had designed. Man, while uninformed, does shrink from destruction, and knows that it awaits himself: but means are placed within his reach, if he would but look for them, by which, freed from all risk, he might go on his way rejoicing, till, reaching the appointed goal, he lays himself down in peace, and resigns his spirit to Him who gave it. Yet, how blind is man! The indulgence by one man of that curiosity which is implanted in him by the Creator himself, is by another scouted as vain philosophy! If one man attempts to turn to a new page of Nature's book, and dares to announce discovered truth, another speedily comes forth to condemn even the opening of the book at all; and because truth oversets his prejudices and his dogmas, instead of casting them away, he grasps them the closer, and shouts aloud, in destructive spirit—Infidel! Atheist!

We beg pardon of the reader; we were nearly leaving our theme behind us, and plunging into a region where we have no present business.

It is obvious that the last great breaking up of the globe took place before man appeared upon it. He was formed to enjoy the existing order of things—what Nature presented in all her aspects, and adapted as his race multiplied, to prefer the regions of perpetual ice, or the heat of the equator. Animal and vegetable life were constituted for every climate—for every scene. The surface of the globe having been fixed, after a convulsion of a magnitude that may have changed its axis, (for we may trace the progress of the rushing of waters which would certainly follow such an event,) we find that, in the destruction of a former surface, provision was made for the formation of soil on the new one. Abundance of loose matter was deposited, and in it vegetation commenced, scanty at first. Plants drawing much of their sustenance from the atmosphere, lived and died after rendering gaseous matter solid; and thus the soil became gradually enriched, and in the course of advancement towards fitness to receive greater variety, others we may suppose were supplied, till, at last, the earth being covered by objects, some of the most delicate beauty, some of stately magnificence, animal life at length appeared, and all was prepared for the being who was to enter on the splendid stage to admire and to adore.—*G.*

WE are assured that many admirers of the POLYANTHUS flower are unsuccessful in its management, simply because they do not study the habits of the plant. It is next to impossible to grow it in a warm sunny situation; it may be done in early spring, but after blooming time it is extremely susceptible of drought, and exposure to a July sun lays it open to the attack of red spiders, which is often fatal to it. The *habitat* of its relation will give some idea in what manner it ought to be treated. The "Pale-faced Primrose" affects sunny banks, it is true, flowering at a season when other vegetation has made but little progress. But who sees Primroses after their blooms have passed away? Sheltered and hidden from the summer heat by the rank vegetation which usually springs up around them, retiring, as it were, beneath the friendly shade of Briars and overhanging bushes, they escape the attacks of those maladies to which their tribe are subject when exposed. This, then, proves that Polyanthuses may be grown to advantage in borders fully exposed to the sun, provided, after a certain period, they are artificially shaded. We have seen them grown and flowered most beautifully by simply having a moveable shade placed on the north side of the bed in the winter and early spring months, and removed to the south side when the sun became too powerful. The situation where we grow a choice collection, is under a bank running due north and south; the bank is crowned with a thick hedge, and the subsoil is a strong retentive clay; on the east, the border is overhung with Plum and other fruit-trees. As a matter of course, till the trees are in full foliage, the plants get the genial rays of the morning sun, which in their early growth is so essentially necessary; and when they most need shelter, these trees, thickly covered with verdure, give them the requisite protection, thus in a great measure imitating their natural habits.

A suitable situation is, we are convinced, half the battle for the successful cultivation of Polyanthuses. Often has it been our lot to witness the vain attempts of people to grow them. They were unremitting in their attention, and their composts were after the most approved receipts; still, all efforts appeared to be attended with a sort of fatality, for after the plants had flowered they began to assume a sickly hue, and eventually became diseased and curled, arising from improper exposure and the subsoil being of too porous a nature.

These details may appear uncalled for to our more practised Floricultural friends, but we are sure that simplicity of description, joined to the repudiation of all quackery, will do more to create a taste for these "gaily-laced" flowers, than the most elaborate and highly-coloured delineations.

We lately noticed a few of the leading varieties which had at various times come under our observation, and to those who may not be conversant with the properties required to constitute a good Polyanthus, or show-flower, we will for their especial benefit and information endeavour to describe them.

The plant itself ought to be in fine robust health, the leaves of a dark-green colour, the rib up the centre of each being clean and semi-transparent. The stem, rising stoutly from the heart, should bear its truss of flowers erect, without being "drawn" or requiring support to enable it to stand. The pips or flowers ought to be in number from five to fifteen, forming a head slightly convex. Superficial observers would suppose that the flower was composed of five distinct leaves or petals. The corolla, however, is monopetalous, with five deep segments, thus forming five apparent petals. We have seen diagrams at various times representing the flower as having six segments; but this is unusual; when it does happen the blooms have a crowded frilled appearance wholly at variance with the flat even character, which is one of the requisites desired by the best cultivators. The centre of the flower must be of a fine clear yellow, more or less intense, without those shades or streaks of reddish brown, observable in some seedlings, and which is very apparent in both the Cowslip and Primrose. The tube is best when surrounded by a slight collar, having, as it is technically termed, "a trumpet eye," conspicuous in the old variety "Tantarara." Some sorts are destitute of such distinction, but this "moulding" as it may be styled, gives a decided finish to that part of the flower. It is also requisite that the thrums or stamens fill the tube, concealing the stigma. This is a point of great importance, as however good its other properties may be, a show-flower in which the stigma prominently occupies the centre—when it is termed "Pin-eyed"—is considered worthless. The segments of the corolla must not cut farther than the body colour or dark ground of the petals; should this be the case the yellow centre has a cracked unsightly appearance, which is often the defect in an old flower styled "The Yorkshire Regent." The ground-colour ought to bear a fair proportion to the eye; in some it is too small, take for instance Lakin's George Canning, alias Clegg's Lord Crewe, in which the yellow is out of proportion. As for shape, the petals, if possible, ought to form as near as may be a perfect circle: those varieties making the greatest approach to this desideratum, of course are best; each petal being margined with a clear yellow lace, similar in colour to the eye, which also strikes from the circumference to the centre through the middle of each. In some cases this lace is neat and even, as in Crowshaw's Invincible, Hufton's Squire Ray, and Cox's Regent; in others, broad and often coarse, as Nicholson's Gold Lace, and Hudson's Morning Star. There is yet another property we would allude to before closing these remarks—it is indispensable that the colours should retain their brilliancy to the last, or in other words "die well." The lace or edge of some varieties is apt to fade, and become of a different shade to the eye of the flower, even when in a state of apparent freshness; this is a serious drawback on the other good qualities, and we are sorry to record that those two fine flowers, Fletcher's Defiance and Nicholson's Bang Europe, are liable to this objection.—*W.*

IT will be seen by an Advertisement in another column, that the Meeting held last Saturday on behalf of the late Mr. Loudon's family, promises to produce all the advantages that were anticipated from it. The names of a large number of noblemen and gentlemen were mentioned as having already become purchasers of Mr. Loudon's works, and among them those of Prince Albert, the Dukes of Devonshire, Northumberland, Sutherland, and Leinster; the Marquesses of Northampton and Waterford; the Earls of Auckland, Fitzwilliam, Burlington, Radnor, Derby, Fortescue, Mexborough, and Aboyne, with a large number of other noblemen and gentlemen.

A money subscription was also opened, with the names of His Grace the Duke of Devonshire, President of the Horticultural Society, for 25*l.*; J. Cook, Esq., of Brookland, for 20*l.*; Mr. Paxton, for 10*l.*, &c.; and a Committee was appointed to carry into effect the resolutions of the Meeting. We trust that the example of London will be followed by Edinburgh and Dublin. It gives us great pleasure to add, that the sum subscribed, either in money or purchases of books, since the subject was first mentioned in the *Gardeners' Chronicle*, now amounts to £614 11*s.* 6*d.*

RANUNCULUSES.

THE following notes were taken from the private memorandum book of an extensive and successful cultivator of that neat and beautiful Florists' Flower, the Ranunculus, and as the observations were penned in the sunny hours of June, while the ardent admirers of this flower were encircling their respective beds, eagerly investigating,

comparing, scrutinising, condemning, or approving the varieties as they unfolded to their view, and all the notes were originally taken for private guidance, and not for publication, they may be presumed, afford some information respecting the merits of the sorts described.

CLASS I.—SELF.

Œil Noir, very fine, dark rich colour.—Nestor, extra fine dark, (one of the best of its class).—Fete Nocturne, rich purple, fine.—Duke of Bedford, large fine formal crimson.—Gibbs's Eliza, very fine straw, extra form, super variety.—Cootar's Apollo, very fine dark; rather coarse in petal.—Tyso's Laureate, very fine, pure yellow.—Comtesse Plaisance, very fine yellow, good form.—Les Vos, dark purple, very fine.—Rosa Montana, superior bright rosy crimson, excellent form.—Tyso's Nivis, fine white.—Cootar's Tippoo Saib, rich, dark.—Condorcet, fine puce purple.—Bouquet Nopparell, dark olive, very fine.

CLASS II.

Flavimorus, cream with purple edge, very fine.—Tyso's Victoria, clear white with crimson edge, very fine.—Aust's Henritella, white, crimson-edged, good shape, very fine.—Horatio, yellow-edged, fine, free bloomer, not quite a pure ground.—Tyso's Herbert, yellow with red edge, very fine.—Temeraire, white, red-striped, (one of the best of its class).—Lightbody's William Penn, white with purple edge, very fine, strongly marked, ground colour seldom pure.—Melange des Beautés, red and yellow-striped, (an excellent old flower, merits well known).—Tyso's Alexis, yellow-spotted, extra fine, good form.—Tyso's Attractor, white, with purple edge, large, very fine.—Kilgour's Queen Victoria, cream, crimson-edged, large, and extra fine.—Cootar's Coronation, buff, pink mottled, very fine.—Grand Monarque, yellow-edged, fine petals, rather loose.—Aust's Nonsuch, white, purple-edged, distinct, very fine.—Tyso's Felix, buff, with distinct spot, extra fine.—Lightbody's No Mistake, cream, purple-edged, strong marking, very fine.—Dr. Franklin, fine clear white, with purple edge, very fine.—Tyso's Edgar, yellow, coffee-edged, excellent form, extra fine.—Quintin Durward, yellow-edged, very fine colours, rather thin.—Tyso's Delectus, yellow, red-edged, very fine.—Lightbody's Rob Roy, cream, crimson edge, very fine.—Imbert, yellow, with faint brown spot, very good.—Tysos Flaminius, yellow, with dark spot, extra (one of the best of its class).—Herald, white, crimson-edged, very fine, excellent shape, high crown.—Tyso's Creon, buff, dark edging, very fine.—Glacia, yellow-mottled, large and very fine.—Paxos, white, with deep purple edge, extra fine.—Biddal's Duke of Wellington, yellow, delicate-edged, very fine.—Macrobius, white-spotted, very fine.—Lightbody's Endymion, white, with delicate rose-edging, very good.—Tyso's Premium, white, purple spot, very fine, high crown.—Aust's Queen Victoria, white, with delicate edging, very fine.—Saladin, fine yellow, with faint spot.—Sophia, or Ma Délice, cream, with rose edge, very good.—Tyso's Vendôme, cream, with dark purple edge, extra fine, rather sportive.—Waterstone's Epirus, yellow-spotted, very fine.

The 50 sorts above enumerated are selected for their quality, without respect to their age or novelty, and they will be found worthy of a place in the collections of cultivators for competition.—*W. J.*

A KNOWLEDGE OF PRINCIPLES ESSENTIAL TO THE BEST CULTIVATION.—No. II.

(*Continued from page* 100.)

An ancient philosopher * on leaving Athens for exile (for advocating the unity of the Deity) exclaimed, "There is a straight road to heaven from every country;" so also is there a straight road to truth from every principle in Nature. It has been already stated, that "every operation in Art is limited in its effect in proportion as it diverges from the line of agency which Nature has prescribed for the same end;" † and such I consider is the result of every process in shifting which seeks to attain the highest effects by a succession of causes, each of which is destructive of an ultimate effect in the one which succeeds it.‡

As it is "the elementary condition of an organised being that favours the mature development of its parts," § so is that development rendered less perfect by every process which retards the operation of its elements; and in every argument to prove that a non-disturbance of functional organs (such as roots, &c.) is essential to perfect and mature growth, we must, consistently with such reasoning, attach an equal, if not stronger importance to such non-disturbance during the earlier stages of growth; because every plant is subject to the law of causal agency throughout its period of life. In short, if the process of shifting prevent plants from appropriating the same amount of atmospheric and solar agency which they appropriated prior to the operation, then such a process (whether considered in a physiological or practical point of view) is an evil, great in proportion to the frequency of its recurrence; and that which is an evil in part is an evil in the whole, as the whole exists but in its parts.

Such conclusions appear to me to be necessarily deduced from the true principles of cultivation, and by such I shall abide until reasons are adduced to show that to produce and maintain a perfect development of the organs of plants "a continued and uninterrupted supply of fluid from the roots" is not indispensable. To hold other opinions would be to abandon the conviction resulting from 15 years' practice, and to forget the experience of my whole professional life.

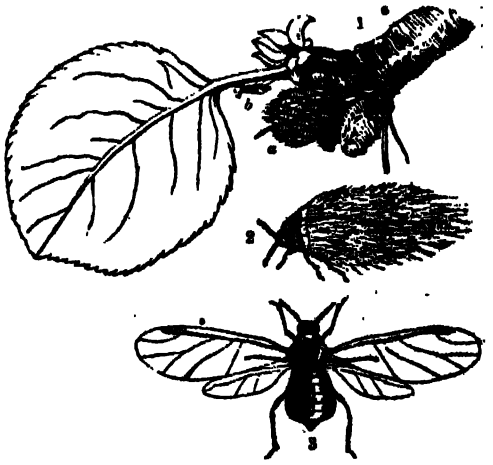
And in what does the evidence of the truth of these principles consist? It may be asked. In the highest effects of cultivation at the present period is the reply; and without presumption, it may be added, that the highest capabilities of nature are based upon the application of those principles. A good illustration of this is to be found in a leading article at p. 391 (1843), where the rapid and perfect attainment of timber by using *buds*, instead of seedlings (or transplanted plants) is adverted to, and furnishes conclusive evidence of the superiority of a progressive and accumulative system of cultivating over all others. It also strikingly confirms the truth that "a constant and uninterrupted supply of fluid from the roots is indispensable" to perfect growth.

The same principle was insisted on in a previous paper, by showing that the only natural mode of perpetuating the primary vigour of plants, is by reproduction *from* seed. In like manner that mode of culture which approximates the nearest to this will be productive of the highest vigour and most perfect proportions. Hence it follows that the several organs of a seed, a bud, a cutting, and a layer, are each possessed of a principle of vitality, varying in power from a seed downwards.

Admitting the correctness of these views, it follows, that since the most valuable results may be attained, by continuing the progressive development of a plant from its rudimentary condition as a seed, such will be the proportionate success attending the imitation of that process in Horticulture.

It has been wisely remarked, that "there is nothing in religion contrary to right reason," and it is equally true that there is nothing in nature contrary to first principles. Much of the difficulty and loss attending their application has arisen from a misapprehension and forgetfulness of the requisite conditions. Men are seldom wise in the exercise of a new power; disappointment is the inevitable result of an injudicious application of powerful agencies, which also meet the counter influence of successful, but inferior modes of culture. For example: the proprietor of an extensive establishment lost many plants; on inquiry, it was found that the person in charge of them had, in the process of potting, omitted bottom drainage, with the exception of a single potsherd. Many persons would, perhaps, have inferred that the deficiency of bottom drainage was the sole cause, but a better informed cultivator would have withheld an opinion until he had ascertained that no modification or judicious arrangement of the soil could have been made equal to the preservation of the plants. Those who doubt the possibility of dispensing with bottom drainage, may be reminded of the increasing evidence in favour of prepared vegetable matter being rendered subservient to valuable purposes; and further, that one of the most extensive establishments in the world has, in the general cultivation of Heaths, for a long time discontinued lower drainage by potsherds, with the exception of a single one over the hole, and this practice is attended in ten thousand instances with uniform success. These facts are not now quoted either in commendation or disapproval of the custom, but to show that there are modes of culture which hitherto have not been satisfactorily explained. Until this is done, first-rate gardening must be content, as the proverb says, to "make haste slowly."

All improvement is a victory won by struggles, and signalised by conflicts with opposing principles. Hitherto we gardeners have been dealing with only the fragments of a system of cultivation, and not with it as a whole. We have been more restricted by general rules, which are limited in their effects, than guided by principles which are perfect in their application. A principle bears the same relation to truth, that a seed does to a plant, the former being a perfect and necessary condition of nature, the latter a perfect and necessary condition of a vegetable. —*William Wood, Pine Apple Place.*



* Anaxagorus. † *Chronicle*, p. 734. ‡ Ibid., p. 734.

ENTOMOLOGY.—No. LV.

THE AMERICAN BLIGHT.—*(Eriosoma lanigera.)*—Such numerous complaints reach us regarding this pest of the orchard, and so many inquiries are made concerning its economy, that it seems advisable to relate its history, and this is the more necessary, since other species are often mistaken for it, leading to great errors and even mischief to proprietors. Many persons have imagined that the Aphides forming the galls on the Poplars and other trees, are the same as the American Blight, and to prove how essential it is to be well acquainted with these subjects, we will quote Mr. Spence's observations in the "Monthly Magazine," where he says:—"In consequence of the ignorance of the orchard proprietors at Evesham, they cut down all the Poplars in that neighbourhood, seeing that they were inhabited by a cottony Aphis, supposing it was the same as the one infesting the Apple-trees, whereas had they been better informed they might have saved their Poplars, for the insects upon them, of this family, never do the slightest injury to the Apple or any Orchard-tree."

Early in the spring we may find, on close inspection, a cottony appearance in the chinks of the excrescences found on the twigs of Apple-trees (fig. 1, *a*), and by the time the leaves are expanded the crevices in the back often exhibit the same appearance, and this white slimy substance becomes at last so abundant that threads are drawn out by the wind, very probably containing the embryo young, which soon people the adjoining trees; such, however, is not always the mode by which the disease is communicated. On examining one of these cottony masses, a number of the wingless females will be found, generally closely packed over one another (*a*), their heads being concealed, and smaller ones are running about; the old sluggish females (fig. 2) are of a reddish or plum-colour, with two short six-jointed antennæ and six legs, but nearly the whole of the body is clothed with long white filaments, I believe of a resinous substance, which project far beyond the apex of the abdomen. These females, like all the Aphides, are furnished with a proboscis, which in this instance is tolerably long and stout, and being insinuated through the tender bark it sucks like a syphon, by which the sap is conveyed into their soft and expansive bodies. By exudation, and possibly the natural evacuations of the animals, they are plentifully surrounded with a reddish liquor, forming globules, and by repeating the animals the same-coloured fluid is reproduced from their bodies.

It is often asked, how the American blight is conveyed to localities where it had been previously unknown, or had been eradicated for a long succession of years? conceiving, as many do, that it is entirely a wingless insect. This pest is no doubt frequently introduced with a young tree, which, however clean it may appear to the careless observer, may contain the latent germs of disease; but there are other causes—I had repeatedly examined Apple-trees, in order to find winged Eriosoma, and after many attempts I discovered them in July and August, in the nests with the wingless females and in considerable abundance. I have little doubt that later in the season winged females may be produced, since such is the case with most of the plant-lice, and if my conjectures be well founded, their appearance in fresh localities is at once explained. The winged males (fig. 3) are pale-green, the head and eyes are black, and the back of the thorax is pitchy, often powdered over with white, becoming cottony on the abdomen, which is broad, the apex pointed; the tubes are wanting, which has led to its separation, with some others, from Aphis, under the generic name of Eriosoma, woolly body; the wings are transparent and iridescent, the superior are very long and ample, with a green stigma, one large marginal cell, a furcate nervure near the tip, the basal branch not reaching the subcostal nervure, and there are two transverse ones approaching each other at their origin, but remote at the outer margin; the inferior wings are small, with a subcostal nervure, sinuated towards the apex, and two oblique nervures on the disc; the antennæ and legs are pale greenish-ochre, rather short and slender, the former are filiform and composed of seven joints, the third elongated; the hinder legs are not elongated, and the tarsi have two joints and are terminated by minute claws; *a* and *b* show the natural sizes of the sexes, and I find the absence of the abdominal tubes, and not the simple apical nervure, is the best characteristic of Eriosoma. I, therefore, expect the Elm-tree gall Aphis will be included in that group and not in Cinara.

It is said that the females begin to lay their eggs in the middle of August, previous to which period I suspect they are viviparous; they are deposited in the crevices of the bark or in the excrescences, and I suppose remain until the spring before they hatch; but it has been asserted that they are breeding throughout the winter, and Salisbury, who seemed to be well acquainted with their economy, states that the young Aphides may be found at all seasons amongst the roots of the Apple-trees. The American Blight loves sheltered spots, and increases most rapidly in valleys and on dry soils, and is said to be much less frequent on strong cold clayey lands. The Codlin and Sweet Apple-trees are its favourite haunts, and it will not, I have heard, attack the Crofton Pippin or Wheeler's Russet. Can this be owing to the smoothness of the bark?

To free the roots they should be partially exposed to the frost and cold, and the application of night-soil and the ammoniacal draining of stables will effectually remedy the evil in that direction. About the end of February the trunks and large branches should be well scraped, the excrescences cut off, and the whole be well scrubbed with soap-suds, after which the same parts may be washed over with a good coating of lime and water, until there is a regular white deposit upon them; when this has been done with attention, and repeated where the slightest re-appearance of the Blight has been detected, I have never known the process fail. Those who prefer it may use Tobacco-water, oil and soot, clay and water, or gas-tar; soap-lees, and oil of turpentine, in proportions of three to one, or one part of vitriol to seven parts of water, have also been strongly recommended as washes; but the great secret in curing this disease is to penetrate every crevice with the brush, and to repeat the application two or three times if necessary,—by perseverance the enemy must be defeated.—*Rusticola.*

THE ROSE GARDEN.—No. VI.

(*Continued from p.* 101.)

[By an oversight a part of this paper was printed last week. It is now repeated.]

Mixture to heal Wounds, and mode of Application.—Five-eighths of black pitch, one-eighth of resin, one-eighth of tallow, one-eighth bees'-wax:—or, half bees'-wax, half pitch:—or, one pound of white Burgundy pitch, a quarter

of a pound of loaf sugar, a quarter of a pound of treacle, a quarter of a pound of bees'-wax, two ounces of allspice, one ounce of pounded ginger, half an ounce of saltpetre. Either of these mixtures may be warmed in a small pipkin, upon a moderate fire, and left to melt for three-quarters of an hour. When it is well melted, but not too hot, the extreme point of each stock should be dipped in it, so as to leave the thickness of two or three sheets of paper of mixture at the end; or if the stocks be planted, it may be laid on with a brush.

Planting Out.—The stocks being collected, should be laid even according to their several heights on the ground, a trench dug, and a row of the tallest stems placed in it, and in front of that another row of the next size, until all are planted out—care being taken to leave sufficient room between each line for the operator to pass in and out without much difficulty; the earth may then be trodden down, and the plants attached to each other line by line, with a long osier or hazel, in the same manner as the top bar of an iron railing connects the uprights, and they will then be preserved from injury by the wind. The earth in which the stems are placed should have been previously well manured, and time given to permit it to be completely absorbed and amalgamated with the soil.

Shoots.—Stocks planted in November begin to push in the March following; those much later entered, viz., after February, are delayed three weeks or a month. At the time the buds begin to appear it is necessary to look over the stems, from time to time, leaving only those buds which are to be worked, as too many would spoil the appearance of the plant, from starting too low down the stem. The desirable number is one or two to a weak plant—three, four, or even five, to a strong one. If two, they should be opposed to each other; if three, they should form a triangle; if four or five, they should be as nearly as possible equidistant from each other, like the points of a spur-rowel, and all the shoots should be full, free, vigorous, and as near the top of the stem as possible—the lowest being not more than three inches under the upper one; thus a proper shaped head will be formed at once. The remainder of the buds should be rubbed off as they appear, and before they have started above half an inch; and all suckers should be eradicated the moment they are seen.

The reasons for permitting two, three, or more shoots to push, are obvious. First, they make a handsome plant by so doing at an earlier period; secondly, the plant itself occupies less room from its head being rounder; and thirdly, as gusts of wind, slugs, snails, deficiency of sap, with a variety of other causes, frequently destroy a bud after it has taken, if one shoot only were permitted to grow and be worked, many plants would lose a season from accident, whereas it sometimes happens that two out of three buds of delicate sorts will go off, and the third remain vigorous. If a single bud carries the whole strength of the tree, it will also frequently make such a shoot the first year, as shall become so woody at the bottom as to induce the operator to allow it to run too far from the graft, and thus make his plant of a different height to what he intended. This, however, is less likely to occur in England than in France, where the growth of the Rose is much more rapid, and may be obviated by stopping the bud when an inch long, by nipping off the top, which will cause three or four eyes to break, and form a head at once.

(To be continued.)

FAMILIAR BOTANY.

Morphology.—No. IV.

It would be unjust to Goethe, and to his fame as a poet, if his own poetical but truthful view of the phenomena of vegetable development were withheld; and therefore, before proceeding further, I would beg to quote the following passages from Mrs. Austin's literal version of his famous "Metamorphose der Pflanzen:"—

Mark now the progress—how by degrees the plant
step-wise led up, forms itself to blossom and to fruit.
Out of the seed it unfolds itself, soon as the earth
softly lets it forth into life, out of her fructifying lap;
and to the attraction of light, the holy, the eternally moving
commends the tenderest structure of budding leaves.
Simple slept in the seed the (germinating) power; an incipient
foretype
lay enfolded within itself, compressed within the husk,
root, and leaf, and bud; only half formed and colourless;
then does the dry kernel protect the silent life;
it shoots, striving upwards, trusting itself to the gentle moisture,
and soon rears itself out of surrounding night.
But simple remains the form in its earliest appearance,
still thus, even among plants, is infancy distinguished.
Quickly, then, a successive impulse, arising, repeats
joint upon joint, built up, over the primitive type.
Not indeed always the same; for manifold shoots forth,
fashioned out, as thou seest, leaf succeeding to leaf;
more enlarged, more indented, more distinct in points and in
parts,
which formerly slept scarce shaped, in the lowermost organ.
And so attains it, at first, its highest destined completion,
which, in many a tribe, awakens thy mind to amazement.
Variously ribbed and jagged, on the juicy exuberant surface
free and infinite seems the impulse which causes the growth.
But now, Nature, with powerful hand, suddenly checks the for-
mation,
and gently diverts it towards a higher perfection. [rows,
In slenderer streams now leads she the sap, the vessels she nar-
and quickly the structure betrays the more delicate workings.
The vigorous contracting force of the branches softly relaxes,
and the frame of the stem takes a more perfect consistence.
Loathed, however, and rapid, up darts the slenderer flower-stalk,
and a wonderful picture attracts the observer's eye.
Round in a circle now range themselves, counted or countless,
the lesser leaves, each next to one like it,
The sheltering calyx, pressed round a centre, unfolds,
and, to finish the work, puts forth the gay coloured crown.
And now Nature blooms, in her highest fullest magnificence,
and leads on limb the daughters, upreared in beautiful union.
Wear thy wonder is now, oh, on the flower-stalk, the silver
waves above the slender framework of changing leaves.
But this glorious show is the herald of new generations,
Yes, the gay coloured leaf binds the all-powerful hand.
Gentle now it shrinks in, the most delicate figure,
then on each side strive forward, towards their destined union,
quickly shoot they together, the adhering budding couples,
as in members around the holy altar are ranged.
Myrrhen hovers near, and exquisite odours
stream around, with sweet all-quickening power.
Now, commingled together, swell countless choirs of hymns
of the swelling buds, in the lap of the bountiful mothers,
And here Nature wields the ring of her eternal powers.
but a new one instantly collects itself on the former,
that the chain may be lengthened out through all time,
and that the Whole may have life, as well as each several
Being.

I wish I had the skill to give the beautiful thoughts of the poet in a language more worthy of his genius.—*E. E.*

Home Correspondence.

Pruning Forest Trees.—The subject of pruning is one that deserves much attention from those interested in the management of plantations. Opinions are so divided with regard to its utility or hurtfulness, that it is of great importance that the true theory should be arrived at, and I shall, therefore, in the following observations, endeavour to contribute my quota towards the furtherance of that object. The motives for pruning are, I conceive, twofold:—First and chiefly, to obtain a tall, straight, well-proportioned, bole or trunk, free from knots and snags; and secondly and secondarily, to admit light and air more effectually to the lower branches of the tree pruned, and of surrounding trees, and to prevent the meeting and interference of these lower branches. This latter object is much assisted, and, perhaps, in some degree superseded, by that most indispensable process in Arboriculture, thinning. The question which, when answered, will decide the efficiency or injuriousness of pruning, appears to me to be—"Does the lopping off of a branch increase or retard the general growth of a tree?" To furnish a satisfactory reply to this question is by no means an easy matter, but I shall endeavour to elucidate it somewhat, by adducing a few facts bearing upon the point. The general principles of vegetable physiology are now sufficiently ascertained, and those that relate to the growth of trees are as follows:—The sap is absorbed by the roots, ascends the stem, traverses the branches, is elaborated in the leaves, and descends again towards the root, depositing a new layer of wood, and also the peculiar secretions of the species. If, then, we deprive a tree of one of its boughs, do we not take from it a number of its digestive organs, its leaves? and do we not thereby impair its growth, at least its increase in thickness? A branch, inasmuch as it bears leaves, is a means of productiveness, and not of waste, to a tree; I should, therefore, be inclined to answer in the affirmative, and to say that pruning, to any extent at a time, must be injurious, at least as far as regards increase in diameter. Let us mark the operations of unassisted nature. A single tree, if left unpruned, and allowed to extend its branches on every side, soon acquires a thick massy trunk, and large boughs, but does not increase much in height. On the other hand, when the trees of a plantation are allowed to remain so close together as to prune themselves, so to speak (and I may mention that plantations of Scotch Fir are generally treated in this way in this part of the country), they shoot up well in height but are slender, and of small diameter. Thus we see that a tree suffered to extend itself laterally will increase chiefly in thickness, and that one which is not permitted to do so will increase most in length. There is one point connected with pruning which I do not think has yet been satisfactorily determined. It is this—"Does a tree absorb the same quantity of sap from the ground when deprived of several of its branches, as it did while they formed integral parts of it?" The elucidation of this question would throw some light on the effects of the operation of pruning. Upon the whole, gradual and cautious pruning seems to be necessary to the obtaining of a lengthy, straight, and smooth stem, avoiding, however, the lopping off of any large limb, except in the case of a fork; and I should be inclined to say that such a system of pruning, combined with careful and judicious thinning, will form the best mode of managing wood to advantage. —*Dendrophilus, Roxburghshire.*

Icehouses.—I beg to offer a plan for keeping ice, that has come under my own experience. Having no properly constructed ice-house, I converted to the purpose a building formerly used as a mushroom-house, which is in a dry and shady situation. The first consideration was, how to get a drainage for the water without admitting the outward air. For this purpose I dug, or rather subsoiled the flooring, a foot or more in depth (the deeper the better), leaving it as loose and friable as possible; upon that was placed a layer of sticks and faggots, upon that again was put another layer of straw, lining the sides of the building with straw, so as to prevent the ice from coming in contact with the brick wall. The ice was then carted in and broken quite small, with wooden beaters; when full the door was shut close, and all admission of outward air was prevented as much as possible by straw, &c. In this way, and at the expense of a few pounds, I have preserved ice for 12 and 18 months. I may observe, an ice-house will be more likely to succeed *above* ground than *under*, and when free from the damp and drippings of trees. Ice will not melt in the hottest sun half so soon as in a close and damp cellar. Put a lump of ice into cold water, and one of the same size before a hot fire, and the former will dissolve in half the time that the latter will. The bed for the ice should be 3 feet above the level of the ground, and this bed should consist of faggots, or something that will admit the drippings to be drained instantly off. This is the way they have ice-houses under the burning sun of Virginia, and there they keep their fish and meat as fresh and sweet as in winter, when neither will keep 12 hours, though let down to the depth of 100 feet in a well.—A Virginian, with some poles and straw, will construct an ice-house for 10 dollars, as good. If not better, than those which cost one man of taste as many scores of pounds.—*A. E. W. Delaunay.*

Qualities of Plants.—Will plants imbibe anything prejudicial, or otherwise, if the matter contained in the soil exists in a superabundant quantity in lieu of their proper aliment—or are they sometimes driven, like animals, from necessity, to make use of unwholesome food which alters the constituents of their bodies? All roots, fruits, &c. have their own peculiar uniform taste; such as a Parsnip like a Parsnip, &c., but they differ occasionally in a remarkable degree. *Grapes* (of Pokay) on slate had a peculiar delicious rich flavour. *Parsnips* (Berlin) on sandy soil were very sweet-flavoured and highly esteemed. *Potatoes* (Penzance, Cornwall) grown on a gravelly soil, and manured with sea-weed were excellent, and tasted like new flour. *Celery* (Sandwich) produced in deep sand impregnated with salt, was very different from that grown elsewhere. *Carrots* (Sandy, in Beds) on deep warm sand with chalk bottom, were very sugary. *Strawberries* (Huntingdon) raised in rich moist loam had a most nauseous flavour; and *Jerusalem Artichokes* (Huntingdon) on the same kind of soil had a watery earthy taste. These have been brought prominently under my notice, but other plants, trees, &c. are likewise affected by the soil in which they grow. Firs, &c. grown on wet land are valueless for timber through being deficient of some particular substance, and having too much of something injurious to them.—*Nemo.* [Plants are unable to reject the fluid matters that are presented to their roots, and consequently, where such matters unsuitable to them exist in land, they and their products are necessarily affected.]

Durability of Oak Timber felled in Winter.—I have been again to see the beam No. 1, from which the bark came, as stated in a former Number. The numerals are thus:—1035, old-fashioned figures; the initials R. M. were evidently cut in the wood at the same period, being of the same breadth and form; the date 1035 is cut in two beams out of the same old building, which beams, as well as No. 1, had been squared previously to being used, as the bark taken off was in the hollows where the squaring did not reach. A timber-merchant and builder is now working up much of this old timber a second time to make ornamental woodwork in a church now rebuilding. It is as hard and sound as ever, and much of the Oak-wood mentioned before near Oswestry, proved by dates to have been upwards of 800 years in use, was used again in building a new church in lieu of the old-fashioned wood-framed house. Here is a proof of Oak-timber, felled with the bark on, having been upwards of 800 years in use, re-used, to endure how much longer I cannot tell; but it has been put in a new house, and to adorn the inside of a new Church. The same builder has very lately taken a piece of Oak-bark, quite fresh and sound, from a beam, proved by date to have been in use 300 years. These facts, I should think, would set the question at rest as to which is the best season to fell Oak, when durability is required. I believe I could procure the piece with the numerals and initials on, should any one wish to possess such a curiosity, by paying a trifle to the owner for carriage, package, &c.; but as it is now exposed to all weathers, it will soon go to decay.—*W. Billington, Oswestry, Salop.*

Fastolff Raspberry.—The history of this excellent variety is as follows:—It was discovered 24 or 25 years since, in the garden of Colonel Lucas, of Filby House, near Yarmouth, Norfolk (now the property of the Rev. Gibson Lucas), growing close beside an old Laurel hedge, which has been since removed. The fruit being found to possess most of the excellent qualities Messrs. Youell and Co. describe, Col. Lucas's gardener took great pains to propagate and increase it, and eventually its superiority was so manifest that he ceased to cultivate any but it and the double-bearing variety, which this is not. By degrees, through Col. Lucas's kindness in allowing canes of it to be given away, it became almost the only Raspberry cultivated in the village of Filby, and from thence crept into most of the gardens both of the gentry and cottagers in the neighbourhood. About a year ago, Messrs. Youell and Co. commenced advertising it under the name of the Fastolff, from the circumstance of the Fastolff family having some centuries since possessed and lived at Caistor Castle, now an old ruin in the village of that name adjoining Filby.—*Fair Play.* [The remainder of this letter is an advertisement. The only thing which interests the public is the fact above mentioned.]

Hampton Court.—I take it for granted that your Paper is the legitimate medium through which to advocate the rights as well as to record the professional practices of gardeners; and I therefore beg to complain, on behalf of those of my brethren more immediately concerned, of the prevailing practice of keeping open the *gardens* and palace of Hampton Court to the ungodly portion of the public on the Sabbath-day. I say ungodly, feeling assured that no man that either fears or loves God will so spend the day which He has commanded to be kept holy. I am no bigot, and detest all attempts to enforce any kind of religious observances by dint of any mere authority, either spiritual or temporal; at the same time I think it a great hardship on the respected gardener at Hampton Court and those employed under him to be deprived of the invaluable privilege of the Sabbath-day, and not only deprived but harassed the whole of that, more than any other day in the week, for the gratification of a host of profane Sabbath-breakers, who have no fear of God before their eyes. It is a hardship in my opinion to which no gardener ought to be subjected, and if you could be instrumental in any way in getting the nuisance abated, you

merit the additional thanks of all good men. I am now speaking for the gardeners only, but as I fear your Paper is not the proper medium, I abstain from tracing the evil through other matters, else I might point to many others who are subjected to like annoyance with the gardeners. Even the worship in the Palace chapel is interrupted by snoring, ignorant, and irreligious intruders. I might also allude to the incongruity of a palace and gardens belonging to her Majesty, the recognised head of our "*truly Apostolic and purely Spiritual Church*," being turned into a scene of revelry and profanity on the Sabbath-day. I might inquire, are not Dr. Howley, Archbishop of Canterbury, and the Bishop of London, privy councillors and keepers of the Royal conscience? Why do they not raise their voices against such enormities, and procure the shutting of the gates on the Sabbath-day, that those within may enjoy the Sabbath; I plead for the gardeners—my brethren of the blue apron, and say it is a shame, a scandal, and a hardship (to say nothing of the sin), to deprive them of their Sabbath of rest in the manner now prevalent!—Q.

Sugar Refiners' Refuse.—There are some notes on Sugar Refuse in Malcolm's "Surrey" (vol. ii., p. 109.) He says that it is a very powerful manure, and good and permanent if well spread; if badly spread, and the lumps not broken up, it burns the Grass. "Upon arable land it is thought not to answer." W. Coles, Esq., has used large quantities for three or four years past; he uses it mixed with road-sand—about three loads of road-drift to one of scum, and from 20 to 30 loads of this mixture applied per acre. It costs 4*s.* per load. The Hay crop increased nearly fourfold. This in 1805.—*E.*

New Zealand.—In the *Chronicle* of September, 1843, are statements relative to New Zealand being a desirable colony for emigrants. The inclosed extract of a letter from a relative of mine, written about the same date, and after the late unfortunate collision with the natives, is confirmatory of your opinion. "This country possesses many advantages and good qualities, viz., salubrious and pleasant climate, varied and beautiful scenery, no fall of the leaf, the woods green all the year round, fertile land that will yield two crops in the year, that is will produce in all seasons, and also possessing many sources of wealth not yet properly acted upon, all the benefits of which we shall in due time enjoy. I have seen many scenes here which reminded me of the Highlands of Scotland. Port Nicholson is not unlike the upper end of the Cromarty Frith, but much prettier. I have no doubt that by-and-bye, when things are properly settled, this will be a most desirable country for any one desirous of emigrating, particularly Agriculturists. At present the districts available are generally difficult and expensive to clear, and would not suit a poor man unless he worked hard himself; but when the native question is settled, fertile districts that are known will be thrown open. I should advise any one intending to purchase land to bring out their money and see what they can buy, instead of playing at 'hide hooky' with their all perhaps. For my own part I continue to like the country and climate well."—*J. S., Wellington, New Zealand, September* 15, 1843.

Feeding of Bees.—It will be recollected that the spring months of last year were wet and cold, and continued so up to swarming time; during that period I fed successively my stocks and swarms. I likewise did the same in October, and I have not lost a single stock; on the contrary, they are very quiet, and have plenty of food. The Bees kept more in the hive during the mild weather in December and January than ever I remember them to have done, arising, no doubt, from their having been fed. I was induced to try this plan through reading "Milton's Practical Bee-keeper," a work which all who keep Bees should possess, and follow its directions, for by so doing many Bees' lives would be saved. I agree with the author, that more depends upon the food than the size, shape, or material of which hives are composed. As the season is approaching when Bees may require feeding, those who are inclined to pursue this plan, will soon have an opportunity, and I doubt not that they will reap an equal advantage.—*A Bee Preserver.*

Management of Bees.—Rule 1. Never kill your Bees. Rule 2. Never allow your Bees to swarm. Place an old stock of Bees on the middle of a board large enough to contain three hives, and on each side of the old stock place a wooden hive, nine inches high, and 11 square inside; or a straw hive with a wooden top. The boards forming the wooden hives should not be less than 1½ inch thick. On the top of each of the side hives there should be a hole two inches in diameter, with a plate of zinc to slide over it, or a cork to fit it. Over the hole, in the inside of the hive, should be fixed another plate of zinc, pierced with pin-holes all over it. These small holes are for the purpose of ventilating the side-hives, thereby preventing the Queen from laying her eggs in them. Should the Bees fill the holes, they must be re-opened. The board on which the hives are placed should be so prepared with passages that the three hives may be united or disunited at pleasure by means of slides made of zinc. As soon as the Bees are likely to swarm, open the passage between the middle hive and one at the side, and force the Bees to pass through the latter by stopping up the mouth of the former. When the Bees have filled one side-hive with honey, let them into the other side-hive, and remove the first, now fit for use, by stopping its communication with the middle hive. Slide some sheet-iron under it, and remove it to another part of the garden in the heat of the day, and the Bees will readily return to the parent stock. The honey will be found quite free from larvæ and farina, if the ventilation has been properly attended to.—*C. A. A. Lloyd.*

Bees.—As I perceive by a recent communication from Dr. Bevan, that he has removed from Llanelwy to Montgomeryshire, I am curious to know what arrangements he found necessary for the conveyance of his hives of Bees from one place to the other. If he would be so kind as to afford this information, he would gratify *C. L.* P.S.—Have any tidings been received of the fate of Mr. Cotton's Bees, for whose transport to New Zealand he made such elaborate preparation?—*C. L.*

Societies.

HORTICULTURAL SOCIETY.

Feb. 20.—Sir C. Lemon, Bart., M.P., in the chair. H. Warre, Esq., was elected a Fellow of the Society. From Mr. J. Brewster, gr. to Mrs. Wray, of Cheltenham, was a plant of Lælia superbiens, having a spike about 5½ inches long, of pretty purple blossoms, which, although truly beautiful, were not so well coloured as could have been wished; but it frequently happens that Orchidaceous plants fail to produce their first flowers well, and very possibly this may improve in course of cultivation. This plant, the honour of first flowering which belongs to Mrs. Wray, and which has created so much interest, is a native of Guatemala, where it was first discovered by Mr. Skinner—the finest specimens being in ravines, and growing out of the fissures of rocks sheltered from north-west winds. Some of the plants have bulbs 22 inches high, and flower-stems four yards long having 22 flowers. Mr. Hartweg, who also met with it in abundance in the neighbourhood of Chantla, where it is planted by the Indians in front of their doors and exists in immense quantities, says that the length of the stem, being four yards, is uncommon, and that the average number of flowers in clusters is from seven to fifteen. A strong plant of this is also in flower in the garden of the Society, growing on a block, where it succeeds well. According to Mr. Skinner, it thrives best in a temperature from 55° to 65°. Mr. Brewster also sent cut flowers of Phycella ignea a Chilian bulb, having beautiful bright-red flowers; this is not hardy, but might possibly be made to succeed in a dry border, if planted out at an early period, and protected by sand being laid over the surface of the ground, the great fault of bulbs from that quarter being their making an attempt to grow during our winter. From the same collection was also a Cryptandra, having a fragrance somewhat resembling that of a Hawthorn; a large Silver Medal was awarded for the Lælia superbiens. Mr. J. Robertson, gr. to Mrs. Lawrence, sent Phaius Wallichii, in good condition, having large brown and white blossoms; Oncidium Cavendishianum, that has kept in bloom nearly five weeks; Hippeastrum sulicum, with large red flowers; a variety of Cyrtochilum maculatum, and a large plant of Cymbidium aloifolium. From the same collection were likewise Oncidium reflexum, a Maxillaria, with a pale-coloured blossom; well-grown plants of Dendrobium Wallichii, and D. pulchellum, the latter twining gracefully over a globular trellis, filled with Moss. There was also Bletia havanensis, with pretty purple blossoms, and a well-grown plant of the brilliant scarlet-flowered Centradenia roses, which has the good property of being a very profuse bloomer. Mr. Robertson also sent Begonia manicata, a plant of recent introduction, with pretty flesh-coloured blossoms. This plant, on account of its long white hairs under the leaves, and large brilliant manicate scales, has a curious appearance. Oncidium longifolium was also in the same collection, and a beautiful plant of Epacris variabilis, completely covered with blossom; a Knightian Medal was awarded for the three last. From Mr. Kennington, gr. to F. G. Cox, Esq., of Stockwell, was the rare Phalænopsis amabilis, on a block, having very conspicuous large snow-white blossoms. From the same were also Huntleya violacea, Cyrtochilum maculatum, a pretty plant of Phaius intermedius, Bletia Tankervillii, and Brassavola nodosa, with small white and green flowers; a Banksian Medal was awarded for the Phalænopsis amabilis. Mr. Gaines, of Battersea, sent for exhibition seven varieties of Camellias. From Mr. W. Scott, gr. to C. Barclay, Esq., was a cut specimen of a flower from a bulb sent from Peru by Mr. Hartweg, having a stem about three feet high, with curious green and red blossoms; a Certificate was awarded. From Mr. J. Wells, gr. to W. Wells, Esq., were cut flowers of Camellias, and a fine plant of an Enkianthus, quite covered with pretty flesh-coloured bell-shaped flowers, having considerable resemblance to the old E. quinqueflorus. Mr. Fortune found these shrubs growing in abundance on the mountains of Hong-Kong; a Banksian Medal was awarded for the Enkianthus. Mr. J. Plant, gr. to J. H. Schroder, Esq., of Brixton, sent a very large specimen of Epidendrum odoratissimum, having a fine panicle of dingy yellow blossoms; a Certificate was awarded. From Mr. Henderson, of Pine-apple-place, was a beautiful small plant of Epacris impressa alba, the pretty Erica mutabilis, remarkable for its long season of flowering; Begonia manicata, B. coccinea, with brilliant scarlet flowers, a beautiful plant of Dendrobium nobile, completely covered with blossoms, and a specimen of Franciscea latifolia, which besides possessing the agreeable fragrance of F. Hopeana, is a free grower; a Banksian Medal was awarded for the two last. Mr. Ayres, gr. to J. Cook, Esq., sent two seedling Cinerarias, one being a bright blue, and the other a purple. From J. Allnutt, Esq., was an excellent specimen in a large pot, of the double white Primula, the leaves of which being of a bright green, were perfectly free from spot, and the flowers were beautifully white; a Certificate was awarded. W. Jackson, Esq., of Salcombe, Kingsbridge, Devon, sent specimens of the Seville Orange, Malta Sweet Orange, Shaddock, and Lemons, that had been grown on an east wall, protected only by a glass frame in winter; they were large, well-coloured fruit; a Certificate was awarded for them. From J. Mouncer, Esq., were nine sorts of Pears, including Fondante Colmar, Ne plus Meuris, Jean de Witte, Merveille d'Hiver, Beurré d'Aremberg, Gloat Morceau, Beurré Rance, Beurré Beurré, and Winter Nelis, all in excellent condition; a Certificate was awarded for them. Dr. Henderson sent an English specimen of Tuck's Cap Gourd for exhibition. From the garden of the Society were Dendrobium nobile and cucullatum, Epidendrum cochleatum, Oncidium cucullatum, a pretty plant of Phaius grandiflorus; Spiranthes cernua, sent by Mr. Hartweg, and a species of Stenomesson from the same; also plants of Epacris nivalis, E. campanulata alba, and a striking Epacris, with two pretty plants of the double pink Primula sinensis that were raised from cuttings struck late in autumn. The soil in which they are growing is mixed with superphosphate of lime, which seems to be more beneficial to plants than any substance of a similar nature yet discovered. There were also flowers of Chimonanthus fragrans, grandiflorus, and parviflorus. Cuttings of the following fruit-trees from the garden were also distributed, viz., Werder's Early Heart Cherry, a very fine large black heart-shaped Cherry, which ripens much earlier than the May Duke. It was received from the Continent, and, according to Baron Truchsess, was originally obtained from the Royal Prussian gardens so long back as 1794; yet it is scarcely in cultivation in this country, where it was not known until introduced by the Society. Along with this was also distributed the Early Purple Guigne, Ickworth Imperatrice Plum, and Royale Hâtive Plum; the latter is exceedingly rich, resembling in appearance the Reine Claude Violette; but it ripens earlier and the shoots are very downy, whereas those of the R. C. Violette are quite smooth.

LINNEAN SOCIETY.

Feb. 20.—The Bishop of Norwich in the chair. A collection of specimens of dried fruits were exhibited, presented to the Society by Dr. Boott. A paper was read on Asiphonia, a new genus of plants belonging to the family Aceraceæ, by W. Griffiths, Esq. A description of the genus and of the species A. piperiformis was read. This plant, besides the structure of its flowers, which are remarkable, presents some peculiarities in its stem. The pith is very large, and the wood is disposed in a wedge-shaped manner, with large medullary rays interposed. A second paper was read from Mr. Griffiths on Hydnora, a genus belonging to the natural order Cytinaceæ. The species examined was the H. Africana, which the author had received from Mr. Harvey, from the Cape of Good Hope. Although this plant had been described by Brown, and figured by Bauer, the author had ventured on another description. The plant is parasitic, mostly on Euphorbiaceæ. The anthers had been described as multilocular, but such a view he did not consider consistent with their structure. The pistillum is altogether one of the most remarkable in the vegetable kingdom. The stigma has a peculiar stellate arrangement, similar to Papaver and Nymphæa. It was looked upon as multicarpellary, but the author was inclined to think the whole pistillum was formed from a single leaf. The placentæ were not, as described by Endlicher, parietal, but were free and pendulous, with their whole surface covered with ovules. This would form a fact opposed to Schleiden's placentary hypothesis. Meyer had supposed that the ovarium was composed of three parts. The two papers were illustrated by drawings.

BOTANICAL SOCIETY OF LONDON.

Nov. 17, 1843.—The President in the Chair. Dr. Bromfield presented a species of Calamintha, new to the British Flora, discovered by him in the Isle of Wight. Read, "Notes of a Botanical Excursion in Warwickshire, Worcestershire, Wales, and Ireland," by Mr. S. P. Woodward.

Reviews.

Mrs. Loudon's Glimpses of Nature (Grant and Griffith) is an account of the natural and other curiosities observed by the authoress during a visit to the Isle of Wight. It contains much agreeable information concerning the plants, shells, birds, and insects; the houses, streets, men, and places, that were met with; and we recommend it to the favour of those who are going to the Isle of Wight, as a useful "handbook" for their children.

The Tree-Lifter; or, a new Method of Transplanting Forest Trees. By Colonel George Greenwood. 8vo. Longmans.

If this book were the production of a person whose life was known to have been spent in researches into Vegetable Physiology, we should give him credit for the justness of some of his views, blame him for his crotchets, and censure him for his want of acquaintance with the works of modern writers. If it were the work of a logician we should cavil at his argumentation, and quarrel with his *non sequiturs*. But the child of an officer of the Household Brigade, who has had other duties to attend to than those of reading the works of Vegetable Physiologists, or studying Archbishop Whately, may claim to be measured by no other standard than that of utility and good sense. Thus measured, Col. Greenwood's book is much above the standard.

It may be looked at in two points of view,—the practical and the physiological.

The practical part consists, firstly, of directions for employing a new kind of plant-lifter, which is so simple, "that a day labourer may use it, and plant daily a tree of from 25 ft. to 30 ft. high;" for the construction and application of which we refer to the work itself. Secondly, of instructions for pruning fruit-trees, which we are happy to

and, in all essential respects, similar to those which have been constantly advocated in this Journal; and thirdly, of directions for transplanting, in which there is much excellent advice; but also several things in which we cannot concur. The gallant author's opinion concerning the action of roots, appears to us more especially a mistake, as we hope to show on another occasion.

In the physiological division of his book Col. Greenwood discusses the function of leaves and roots, most justly objects to the opinion that leaves are essentially organs for absorbing moisture, as Bonnet and Liebig have asserted, demonstrates as others have done before him, the error of supposing that sap rises only by the sapwood of trees, and cleverly disposes of the new exploded doctrine of root-secretions. We must quote his remarks upon the latter subject.

"I should doubt the supposed excretion from the roots of substances unnecessary to the growth of the tree. If this were so, the roots would soon be surrounded with such substances, and would be incapable of absorbing nutriment. In chalk districts eternal woods are found composed of nothing but Beech; in other soils of nothing but Oak. The oldest Vineyards and the oldest Hop-gardens are the best. (I say nothing of old meadows, since trees are in question.) In all these cases, if the roots excreted substances unfit for nourishing the plants, the whole soil would have become saturated with them. Land-plants grown in water are always unhealthy. Under these circumstances, may not colouring matter, or other substances supposed to be excretion, be the result of disease and decay, or partial maceration of the roots. There is no discoloration of the water in which the seedlings of forest-trees are made to grow.

"I imagine that the roots of trees, in absorbing the moisture with which they come in contact, give off the unnecessary parts of this by transpiration in the air. I do not perceive what should cause roots to transpire when surrounded by moisture, or if they do, they must return like the dog to his vomit, and again absorb their own transpirations."

This kind of argument, added to the experimental denial given to the statements of Macaire, which, however, Professor Liebig regarded as *necessarily as well as experimentally true!* must we think put an end, in this country at least, to all speculations upon the subject.

Colonel Greenwood considers the worst time to transplant a tree to be when it is shooting, and the best time to be as soon as possible after it has shot; *that is, as soon as it has formed its winter bud:*—

"This will differ in different trees. Some are fit to transplant in June, or even in May. The best months for transplanting the generality of English trees with the ball of earth, are July, August, and September; for though the upward growth has then ceased, the growth in diameter, and the downward growth, that is, the elongation of the roots, is in the fullest tide."

This is to a certain extent our own view of the question (see Theory of Hort., chap. 16), although our reasons are different; but we cannot go to the same length as Colonel Greenwood, in the absence of evidence, which he does not give. For we cannot regard as evidence the statement that he has transplanted trees of about 25 feet in height in *every* month of the year without a single failure, and without the plants feeling their removal. We have no doubt of the fact; Colonel Greenwood's assertion is sufficient; and, in the absence of his assertion, we should think it probable. But what we want to know, and what we do not find mentioned, is under what exact circumstances these trees were removed; how long they lived, and what sort of growth they made the following year,—very material points for consideration.

These, however, and some other questions, we reserve for future discussion. In the meanwhile, we cannot but express our regret that more men, with the clear views of Colonel Greenwood, and the same habit of thinking for themselves, do not apply to the study of a subject so useful as Vegetable Physiology, so capable of conveying exquisite pleasure, and which is, to use his own forcible language, of "the first importance to the existence of man and the honour of his Creator."

Miscellaneous.

The Gladiolus.—The Gladiolus communis, a native of the south of Europe, is very generally known, and is to be found in the most humble cottage-garden. Such is, likewise, the case almost with the G. byzantinus, introduced two centuries ago, from the environs of Constantinople. These two species have afforded a great number of varieties of different shades, such as white, rose-colour, orange and vermilion, purple and lilac. Their varieties are all of easy cultivation, and will endure the winter in the open ground provided they are in light and rather dry soil. They require a change of soil and situation every two or three years: for experience proves that by this treatment the number and size of the flowers are increased, and their colours become brighter and more distinct. Towards the middle of the last century, new species of Gladiolus began to be introduced from the Cape; but their merits were not such as to render their cultivation general; and few of them are now to be met with, except in large collections and botanic gardens. The object of the present communication is to point out more especially those varieties of Gladiolus which, instead of being consigned to oblivion or only noticed by the amateur with indifference, merit, on the contrary, his care and attention. They are Belgian productions, resulting from judicious crossing. By this means various new varieties have been obtained which surpass the finest we hitherto possessed of the genus, mainly the G. cardinalis and floribundus, introduced from the Cape in 1788 and 1789, and the G. ramosus. The G. psittacinus, perroquet, or Duchesi, was introduced after this period. It was brought from Java, in 1823 or 1824, in a Dutch vessel, to Rotterdam, and having been obtained by Dr. Desl. of Brussels, it flowered with him for the first time, and was accordingly named after him by Horticulturists. In addition to Gladiolus Colvilli, pulcherrimus, ramosissimus, and a great number of other very fine varieties with which the Horticulturists of Haarlem have enriched the trade, the formosissimus deserves particular notice, as being the finest we have seen in flower in 1842. This variety unites the habit and abundant flowering of the ramosus with the colour of the cardinalis, though scarcely so brilliant. All these varieties have a family resemblance to the ramosus, floribundus, and cardinalis. They are not, however, to be compared with the brilliant novelties obtained at the Duc d'Aremberg's seat, at Enghien. Beddinghaus, a young man of good intelligence and education, and in every respect capable of directing such an establishment as that at Enghien, fertilised the G. psittacinus with the floribundus, the ramosus, and the cardinalis. This crossing was made in the summer of 1837, a season favourable for such operations. Seeds were ripened, and from a sowing of these the G. gandavensis was raised. M. Louis Van Houtte having obtained this variety, thus announced it in his catalogue for 1841:—"I have the stock of this Gladiolus, with the exception of two bulbs possessed by one of my brothers. At the moment I write all Ghent comes to admire it. In stateliness and colour it exceeds all we have seen amongst the Gladioli. Its dimensions surpass those of G. ramosus; its majestic flowers, to the number of 18 or 20, are of the most charming vermilion; their inferior petals, adorned with chrome, amaranth, and brown, are again relieved by anthers of an azure hue, which descends to the centre of the flower." This description, doubtless made in a moment of admiration and enthusiasm, is, however, little exaggerated. If properly cultivated, the plant will produce flowers corresponding with the above description. Many other varieties, from the same sowing, much surpass even the G. gandavensis. Several of these have already appeared in the catalogue of M. Jacob Makoy, of Liége, for 1842. Others are not yet in the trade. The names of the former are Baron de Pronay, De Candollii, Grétry, Herberti, Lowii, Pfeiferii, Reine des Belges, Salmianus, Schwarzenbergianus, splendidus, and Sternii. With regard to their culture, it may be stated that they succeed very well in the open air, planted in leaf-mould. They are taken up towards the end of September, after their stems are completely withered. The offsets and bulbs are preserved during winter in a dry place, protected from frost. They are replanted in the open ground in the beginning of April.—*J. de Jonghe, in Revue Horticole for Sept.*, 1843. ‖

The New Indian Black Dye.—Some weeks since we stated that a new black dye had been discovered in the Shan country, and that a small sample of it had been sent over to this country to the Society of Arts. A report on this new dye, recently laid before that Society by Mr. Edward Solly, appears to bear out the previous statement, by showing that it is really a black vegetable dye.* The quantity sent was too small for any detailed chemical analysis to be made, but its leading chemical properties have been ascertained. Mr. Solly describes the colour as being insoluble in water and all ordinary solvents; but, deoxidised by sulphate of iron and lime, it becomes soluble, like indigo. The colour likewise resembles indigo, in being destructible by chlorine, but differs from it in not subliming like that substance. Careful experiments were made in the hope of purifying it by sublimation, but without success, as the dye was decomposed; but no sublimate could be obtained. When heated, the dye does not melt or soften, but burns with a bright clear flame, emitting a strong and disagreeable odour; hence it plainly differs from the black resinous matters obtained from the Melanorrhœa, and similar trees. The quantity of ash which is left after burning is so small, that it is evident that the dye is a pure organic substance, and that the colour is quite independent of iron or any other inorganic matter. Mr. Solly concludes from his experiments, that it is a new colour possessed of very useful properties, and considers that it is likely to prove a highly valuable dye stuff, if it can be procured in large quantity.

Large Trees.—Measure, &c. of four trees, standing and growing at Nettlecombe, property of Sir John Trevelyan, Bart., January, 1840: *Elm Tree.*—813 ft., or 20 ton 13 ft., is 40 ft. to the fork; a branch at 50 ft. high is 9ft. in circumference; extreme height of tree 100 ft. At 4 ft. from the ground is 17 ft. in circumference. *Oak Tree.*—603 ft., or 15 tons, 3 ft.; its extreme height 80 ft.; at 4 ft. from the ground is 16 ft. 6 in. in circumference. *Beech Tree.*—709 ft., or 17 ton, 29 ft.; its extreme height 100ft., at 4 ft. from the ground is 18 ft. in circumference. *Chesnut Tree.*—373 ft., or 9 tons, 13 ft.; its height 60ft.; at 4 ft. from the ground it is 17 ft. 4 in. in circumference.—*An Elm* at this place, planted about 1770, contains 480 ft.; that is 300 ft. in the trunk, and 180 ft. the top and branches. From the ground to the fork it measures 32 ft., and at 16 ft. high is 12 ft. 4 in. in circumference. The top or principal branch, contains 60 ft. of timber; another branch contains 30 ft., and three other branches 20 ft. each; other branches from 3 ft. to 13 ft. each; other branches not reckoned in the above, but containing about 40 ft., were broken off by the wind in 1843. —*Jas. Babbage.*

Grafting Pelaryoniums.—M. D. Mêline, of the botanic garden, at Dijon, has been very successful in grafting numerous varieties of Pelargoniums on the same plant. This was done in order to possess many varieties in small space. The mode of cleft-grafting was adopted, the parts tied together being of equal thickness, bound with wool, and shaded under glass for a week. On one plant 10 grafts were found all well united in the course of 15 days. A Pelargonium elegans was selected for the stock on account of its vigorous growth. The grafts were put on in 1837; and in 1842 they were still in a thriving condition, their junction with the stock being then scarcely perceptible.—*Revue Horticole for Sept.*, 1843. ‖ [The same thing has been done in this country by Mr. Ansell.]

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSES, CONSERVATORIES, &c.

Where large collections of house-plants are cultivated, repotting takes place every month in the year; but from this time till August is the principal period for this work in a general way. Many plants may now be safely repotted; early in spring the rule of seeing the roots growing freely is the best guide for beginners. Many plants will begin to grow at the top before their roots are in action; yet they do not require to be re-potted; they are either too much confined, or under a higher temperature than they require at this time. Orchidaceæ from the more temperate regions are often much injured by a high temperature when they begin to grow. The heat of the stoves should not exceed 60° by night; indeed 55° is sufficient till all the plants are in full growth.

Conservatory.—Epacrises, Heaths, and others of the more hardy plants in or coming into flower, should be kept near the sources of ventilation; white Roses and other forced flowers fresh from the forcing-pits require the warmest part of the house, and ought to be kept free from currents of cold air at first. This is a good time to take memoranda of the best varieties of forced bulbs, especially Hyacinths and Tulips. The nights are still too long to allow any syringing in the afternoons; but such plants as are not in flower, and all vacant spaces in the house, should be sprinkled two or three times a week, and this should be performed early in the day.

Greenhouse.—The plants here may now have a slight syringing in the afternoon, and air may be freely admitted on all fine nights. Some young plants may want repotting. If some are growing freely at the top, and the roots not in action, the house is too hot for them, and you must remove such plants to a cooler place. Attend to neatness in all the houses, and make it a rule never to pass a pot plant through your hands without removing all yellow or injured leaves, if there are any on it; also insects, or weeds growing in the pot.

Forcing-pit.—This is a good time for propagating many plants by cuttings, by grafting, and by seeds; and the forcing-pits are the best places for this work. Seedlings already up ought to be potted off as soon as they can be safely handled. Foreign seeds had better be sown in 32-pots, putting four or more kinds into one pot, and placing labels in the middle facing the different seeds. Less water will thus be needed than if each kind was sown in a small pot; and the less water given to doubtful seeds the better chance they will have to germinate. Let every shelf and corner of these useful pits be filled with plants as others in flower are removed from them.—*D. B.*

III.—FLORISTS' FLOWERS.

Auriculas may be kept moderately moist. If not top-dressed as before directed, let them be done immediately. We are trying Potter's Liquid Guano as a stimulant, and shall report the result.

Polyanthuses.—Look well, after the late severe weather. As spring advances, the snails get proportionably troublesome; diligence must be used in trapping them.

Ranunculuses.—Plant without delay. Seed must also be sown—though I prefer autumnal sowing, where there is an opportunity of protecting during winter. Frames covered with calico prepared with Whitney's or some other similar composition, will, I doubt not, afford great facilities in the way of preservation in severe weather. The compost necessary is leaf-mould and loam, equal parts, which has been previously exposed to the action of heat, to destroy insects, eggs, &c., contained therein. Beds about 18 inches by 12, and 6 deep, are most convenient. Fill with compost, and water it well; sow the next day, cover with very fine soil, *lightly*, for if too deep the seed will not appear. After sowing, it must be protected from heavy rains and frost; a cold frame is perhaps the best situation.

Carnations.—Should any soil have lodged in the axils of the leaves it is imperatively necessary that it should be removed; a quill, with the feather stripped off on one side, and cut half off on the other, makes a simple but effectual brush to perform this operation, and by timely looking through the stock disease may be prevented. Planting time is now rapidly drawing on; exhibitors who have not strengthened their weak or deficient classes in the autumn should now look out for the sorts wanted, if they mean to get first prizes or silver cups.

Pinks.—We should much like to see these highly fragrant flowers more extensively cultivated; beds may yet be planted, but the flowers do not usually last so well as those planted in September.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—If in arranging the Pines, the plants for fruiting during May and June, can be put into a separate pit or compartment, they may be kept at a temperature of 60° by night, and 70° by day, which will be sufficient for the present. Be careful that the bottom-heat does not exceed 85°, lest they start into fruit too soon. Syringe the plants now in fruit, shutting up with sun-heat, which you may do with a temperature of 85° to 90°. Shake the plants lately potted, the larger successions when at 80° of sun-heat, and the young at 70°, till they have made a fresh start. A moist atmosphere will now be indispensable. Crowns and suckers growing in the tan should now be potted if strong; but if weak, and you want to keep them, let them remain in the tan a few months longer.

Vinery.—The Grapes on the Vines started in November will now require their final thinning, if not already done, this them well that the berries may be fine, and ripen regular. It is difficult to give directions as to the number of branches to be left to each rafter, as the sort of Vine, age, condition as to healthiness and vigour, require to be taken into consideration. A moderately good crop for early-forced Vines, would be about 12 or 16 good bunches to a rafter of 15 feet. Where the Muscat of Alexandria and other good keeping sorts of Grapes, are in a house by themselves, and the house not used for Pines, it would improve them in flavour, and they would be in a better condition for keeping through the next winter, if they were started earlier than the late-house generally is. I would recommend starting them now, and give them plenty of time to ripen. Where they are grown over Pines, keep them cool till they break by the natural heat of the atmosphere, when they will bear, with less injury, the heat necessary for the Pines.
